Necessary and Sufficient Conditions for the Existence of a Lagrangian in Field Theory. I. Variational Approach to Self-adjointness for Tensorial Field Equations*

RUGGERO MARIA SANTILLI‡

Laboratory for Nuclear Science and Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

Received June 1976

In this paper we identify some of the most significant references on the inverse problem of the calculus of variations for single integrals and initiate the study of the generalization of the underlying methodology to classical field theories. We first classify Lorentz-covariant tensorial field equations into nonlinear, quasi-linear, and semilinear forms, and then introduce their systems of equations of variation and adjoint systems. The necessary and sufficient conditions for the self-adjointness of class $\mathcal{C}^2$, regular, tensorial, nonlinear, quasi-linear and semilinear forms are worked out. We study the Lagrange equations, their system of equations of variations (Jacobi equations) and their adjoint system by proving that, for class $\mathcal{C}^2$ and regular Lagrangian densities, they are always self-adjoint. We then introduce a concept of analytic representation which occurs when the Lagrange equations coincide with the field equations up to equivalence transformations and refine the definition by particularizing it as direct or indirect and ordered or nonordered. Some of the conventional cases of tensorial fields are considered and we prove, in particular, that the conventional representation of the complex scalar field in interaction with the electromagnetic field is of the ordered indirect type. For the objective of identifying our program we recall the two classes of equivalence transformations of the Lagrangian densities which are primarily used nowadays, namely, the Lorentz (coordinate) transformations and the gauge transformations (transformations of fields within a fixed coordinate system), and postulate the existence of a third class, which we term isotopic transformations of the Lagrangian density and which consist of equivalence transformations within a fixed coordinate system and gauge. We finally outline the objectives of our program, which essentially consist of the identification of the necessary and sufficient conditions for the existence of a Lagrangian in field theories and their first application to the transformation theory within the framework of our variational approach to self-adjointness.

1. Introduction

The inverse problem of the calculus of variations can be formulated as follows. Given a family of \( \infty^m \) paths \( x_k(x), k = 1, 2, \ldots, n \), solutions of the system of ordinary second-order differential equations

\[
F_k(x, y, y', y'') = 0,
\]

\[
y' = dy/dx, \quad y'' = d^2y/dx^2,
\]

(1.1)

determine whether these paths can be identified with the totality of extremals of a variational problem

\[
J(y) = \int_{x_1}^{x_2} dx \, L(x, y, y').
\]

(1.2)

A physical significance of this problem within the framework of Newtonian mechanics is that its solution provides the means to ascertain whether, given a system of Newton's equations of motion in configuration space [1]

\[
F_k = A_{kj}(t, q, \dot{q}) \dot{q}_j + B_k(t, q, \dot{q}) = 0,
\]

\[
\dot{q} = dq/dt, \quad \ddot{q} = d^2q/dt^2,
\]

(1.3)
a Lagrangian \( L(t, q, \dot{q}) \) for the analytic representation [2]

\[
L_k = (d/dt)(\partial L/\partial \dot{q}_k) - (\partial L/\partial q_k) = A_{ki} \dot{q}_i + B_k = 0, \quad k = 1, 2, \ldots, n
\]

(1.4)

exists and, in case of an affirmative answer, it provides the methodology for its computation.

The present status of the investigations on this problem within the framework of Newtonian mechanics is reviewed and somewhat expanded in a forthcoming monograph by this author [3].

This problem for the case \( n = 1 \) was first solved by Darboux in 1894 [4], and subsequently expanded to higher derivatives by Hirsch in 1898 [5] and Bohem in 1900 [6]. The case \( n > 1 \) has been studied by several authors, including Helmholtz in 1887 [7], Mayer in 1896 [8], Königsberger in 1901 [9], Hamel in 1903 [10], Kürshack in 1906 [11], Davis in 1928–1929 [12], and Douglas in 1941 [13].

These authors essentially introduced what are customarily called the conditions of self-adjointness, namely, the (necessary and sufficient) conditions for the equations of variation of system (1.3) to coincide with the adjoint system. Then they proved for the case of regular [14] systems that such conditions of self-adjointness are sufficient for the existence of a Lagrangian for representation (1.4).
The ultimate reason for such effectiveness of the condition of self-adjointness rests on the fact that the Lagrange equations in regular class $\theta^a$ Lagrangians are self-adjoint. This property was apparently established for the first time by Jacobi in 1837 [15]. And indeed, the equations of variations of the Lagrange equations, or, equivalently of the Euler equations of a variational problem, are customarily called the Jacobi equation in the current literature in the Calculus of Variations [16–23]. It is a matter of elementary calculations to see that the Jacobi equations, under the assumed regularity and continuity conditions, coincide with the adjoint system. This establishes the self-adjointness of the lhs of identifications (1.4). Under a suitable characterization of the type of analytic representation they are referred to [3], the conditions of self-adjointness of the equations of motion then became the necessary and sufficient conditions for the existence of a Lagrangian.

Since the Douglas' investigations of 1941, the inverse problem on the calculus of variations has remained virtually ignored in both mathematical and physical literature with very few exceptions known to this author, among them the study by Dedecker of 1949–1950 [25] and Havas of 1957 [26]. This is rather regrettable because the implications of the methodology which underlies the problem are significant.

First of all, the conditions of self-adjointness are insensitive as to whether the acting forces are derivable from a potential or not. Therefore, starting from the conventional structure of the Lagrangian for a conservative (unconstrained) Newtonian interacting system

$$L_{\text{Tot}} = \sum_{k=1}^{n} L^{(k)}_{\text{Free}} + L_{\text{Int}},$$

(1.5)

where $L^{(k)}_{\text{Free}}$ is the kinetic energy of the particle $k$ and $V = -L_{\text{Int}}$ is the potential function, the methodology which underlies the inverse problem of the calculus of variations gives the conditions for the existence of a Lagrangian also when the forces are not derivable from a potential. In this case, however, an "additive" interaction term $L_{\text{Int}}$ to the kinetic energy is insufficient by itself to represent the motion. A structure of the Lagrangian capable of representing this broader class of Newtonian systems is given by [3],

$$L_{\text{Tot}} = \sum_{k=1}^{n} L^{(k)}_{\text{Int},1} L^{(k)}_{\text{Free}} + L_{\text{Int},2},$$

(1.6)

namely, it is characterized by $(n+1)$ interaction terms, $n$ multiplicative terms $L^{(k)}_{\text{Int},1}$, and one additive term $L_{\text{Int},2}$. Trivially, at the limit when all multiplicative interaction terms reduce to unity, the generalized concept of Newtonian interactions according to the Lagrangian (1.6) reduces to the conventional concept of Lagrangian (1.5).
This aspect, however, does not exhaust the significance of the conditions of self-adjointness. For instance, within the framework of the transformation theory for Newtonian systems, such conditions allow the identification of new types of equivalence transformations of the Lagrangian. In essence, there exist infinite varieties of systems of differential equations capable of representing the same path, i.e., all admitting the same general solution. One family of such equivalent equations of motion can be characterized by

$$h_{kj}(A_{kj}\ddot{y}_j + B_j) = A_{kj}^* \ddot{y}_j + B_j^* = 0,$$

$$h_{ki} = h_{ki}(t, q, \dot{q}), \quad \det(h_{ij}) \neq 0.$$  \hspace{1cm} (1.7)

The conditions of self-adjointness establish that for all elements of the family (1.7) of equations of motion which are self-adjoint (but not necessarily identical), the Lagrangian exists. Thus, if a given system admits the analytic representation (1.4) and a self-adjoint equivalence transformation (1.7), then the new representation

$$(d/dt)(\partial L^* / \partial \dot{q}_k) - (\partial L^* / \partial q_k) = A_{kj}^* \ddot{q}_j + B_j^* = 0, \quad k = 1, 2, ..., n$$  \hspace{1cm} (1.8)

exists. The transition $L \rightarrow L^*$ so constructed is an equivalence transformation of the Lagrangian which cannot be derived either with a point transformation $L(t, q, \dot{q}) \rightarrow L'(t, q', \dot{q}')$ (because it occurs within a fixed coordinate system) or with a Newtonian "gauge" transformation $L \rightarrow L^* = L + G(t, \dot{q})$ (because the Lagrange equations in $L$ and $L^*$ do not coincide, unless the mapping is trivial).

As a consequence, the equivalence transformations $L(t, q, \dot{q}) \rightarrow L^*(t, q, \dot{q})$ constructed with the above use of the conditions of self-adjointness constitute a third identifiable layer of the transformation theory in configuration space, besides the conventional point and gauge transformations. Such transformations $L \rightarrow L^*$ have been termed by this author, for certain algebraic reasons, isotopic transformations [3]. It should be indicated here that these transformations result in being the extension to arbitrary (finite) dimension $n$ of the equivalence transformations of the Lagrangian considered by Currie and Salten in 1966 [27] for the case $n = 1$, without the methodology of the inverse problem of the calculus of variations.

From the viewpoint of the generalized concept of Newtonian interactions according to Lagrangian (1.6), the isotopic transformation essentially represent the "degrees of freedom" of the $(n + 1)$ interaction terms within a fixed path. Indeed, the transition $L \rightarrow L^*$ can be written

$$L_{\text{Tot}} = \sum_{i=1}^{n} L_{\text{int},i}^0 L_{\text{Free}}^0 + L_{\text{int},i}^0 \rightarrow L_{\text{Tot}}^* = \sum_{i=1}^{n} L_{\text{int},i}^{a,b} L_{\text{Free}}^{a,b} + L_{\text{int},i}^a.$$  \hspace{1cm} (1.9)
Needless to say, isotopic mappings (1.9) also apply when the original Lagrangian 
$L_{\text{Tot}}$ has the conventional structure (1.5). This, however, implies the transition 
from conventional to generalized Lagrangian structures for conservative Newtonian 
systems, i.e.,

$$L_{\text{Tot}} = \sum_{k=1}^{n} L_{k,\text{Free}} + L_{\text{Int}} \rightarrow L_{\text{Tot}}^* = \sum_{k=1}^{n} L_{k,\text{Int, Free}} + L_{k,\text{Int, II}}^*.$$ \hspace{1cm} (1.10)

A trivial example for the one-dimensional harmonic oscillator $\ddot{x} + x = 0 \ (m = 1; \ k = 1; \ x \neq 0; \ \dot{x} \neq 0)$ is given by [3]

$$L_{\text{Free}} = \frac{1}{2} \dot{x}^2;$$

Structure (1.5):

$$\begin{align*}
L_{\text{Int}} &= -\frac{1}{2} x^2, \\
L_{\text{Tot}} &= L_{\text{Free}} + L_{\text{Int}} = \frac{1}{2} (\dot{x}^2 - x^2);
\end{align*}$$

$$\begin{align*}
L_{\text{Int, I}}^* &= \frac{1}{2} \dot{x} \cos t + x \sin t, \\
L_{\text{Int, II}}^* &= -x^2 \dot{x} \cos t, \\
L_{\text{Tot}}^* &= L_{\text{Int, I}}^* L_{\text{Free}} + L_{\text{Int, II}}^* \\
&= \frac{1}{2} \dot{x}^2 \cos t + \frac{1}{3} x \dot{x} \sin t + x^2 \dot{x} \cos t;
\end{align*}$$

Isotopic Mapping: \hspace{1cm} $L_{\text{Tot}} \rightarrow L_{\text{Tot}}^*.$ \hspace{1cm} (1.11)

This point is indicated to emphasize the fact that, within the framework of Newtonian mechanics, the Lagrangian for the representation of conservative interacting systems must not necessarily have the conventional structure (1.5) because equivalent generalized structures (1.6) are also admissible. Therefore, the generalized concept of Newtonian interactions according to Lagrangian (1.6) has a twofold significance. First, it allows the representation of a broader class of Newtonian interacting systems, and second it is significant for the transformation theory of both nonconservative and conservative systems.

The significance of the conditions of self-adjointness for canonical formulations of Newtonian systems [3] is even more intriguing than that for configuration space formulations. Indeed, such conditions, besides providing the methodology for the identification of a Hamiltonian without any prior knowledge of a Lagrangian, possess relevant algebraic and geometrical meanings. Furthermore, the phase-space image of the above indicated transformations $L \rightarrow L^*$ can be expressed in terms of an invertible Lie algebra axiom-preserving mapping of the Poisson bracket [3] which, in the theory of abstract algebras is termed an "isotopic mapping" of the product. This indicates the reason for the selected terminology.
In these papers we shall initiate the identification of the generalization of the methodology of the inverse problem of the calculus of variations to the case of classical field theory and attempt a preliminary analysis of its possible significance.

Such a problem essentially corresponds to the inverse problem for the case of multiple integrals. Apparently, this problem too has remained virtually ignored in both the mathematical and physical literature. However, due to the vast number of references which exist in the several branches of the calculus of variations, as well as of field theory, this author makes no claim to originality.

2. Notation

We shall denote with \( x = \{ x^a \} = (x^0, x^1, x^2, x^3) \) generic points of the Minkowski space \( M_{3,1} \) with metric tensor \( g^{\mu\nu} : g^{00} = -g^{i\mu} = 1; g^{\mu\nu} = 0, \mu \neq \nu; \kappa = 1, 2, 3; \mu, \nu = 0, 1, 2, 3 \). A generic point set in \( M_{3,1} \) will be denoted with \( R_x \). The closure \( \overline{R_x} \) of \( R_x \) is the union \( R_x \cup \partial R_x \), where \( \partial R_x \) is the boundary of \( R_x \). We shall say that \( R_x \) is a region when it is open and connected and it is a domain when it is perfect, internally connected, and each of its points is a point of accumulation of interior points. Then if \( R_x \) is a region, \( \overline{R_x} \) is a domain.

We shall say that a set of (classical) fields \( \Phi(x) = \{ \phi_a(x) \}, a = 1, 2, \ldots, n \), defined in a common region \( R_x \) is of class \( \mathcal{C}^m \) in \( R_x \) and write \( \Phi \in \mathcal{C}^m(R_x) \), \( m = 0, 1, 2, \ldots, \infty \), when each component \( \phi_a \) possesses continuous (Hölder) derivatives in all coordinates \( x^\mu, \mu = 0, 1, 2, 3 \), up to and including the order \( m \) in every bounded domain contained in \( R_x \). Partial derivatives of \( \phi_a(x) \) with respect to \( x^\mu \) will be denoted with the symbols

\[
\begin{align*}
\phi_a^i &= \frac{\partial \phi_a}{\partial x^i} , \\
\phi_a^{i\mu} &= \frac{\partial \phi_a}{\partial x^\mu} , \\
\phi_a^{i\mu\nu} &= \frac{\partial^2 \phi_a}{\partial x^\mu \partial x^\nu} , \\
\phi_a^{i\mu\nu\rho} &= \frac{\partial^3 \phi_a}{\partial x^\mu \partial x^\nu \partial x^\rho} , \\
\phi_a^{i\mu\nu\rho\sigma} &= \frac{\partial^4 \phi_a}{\partial x^\mu \partial x^\nu \partial x^\rho \partial x^\sigma} ,
\end{align*}
\]

(2.1)

Throughout this paper we shall only consider sets of fields \( \Phi(x) = \{ \phi_a(x) \} \) which can be partitioned into subsets \( \Phi_i(x) = \{ \phi_{a_i}(x) \}, \phi_{a_i}(x), a_i = 1, 2, \ldots, r_i \), \( i = 1, 2, \ldots, r \), each one transforming covariantly under a reducible or irreducible tensorial representation of the Poincaré group

\[
\Phi_i(x) \rightarrow P(A, a) \Phi_i'(x) = \Phi_i(A^{-1}(x - a)).
\]

(2.2)

For instance, \( \{ \phi_a(x) \}, a = 1, 2, \ldots, 6 \), can represent the set constituted by the electromagnetic potentials \( A_\mu(x), \mu = 0, 1, 2, 3 \), a complex scalar field \( \varphi(x) \) and its
complex conjugate field \( \bar{\phi}(x) \), i.e., \( \{ \phi_a \} = \{ A_a ; \varphi; \bar{\varphi} \} \). The case of spinorial fields will be considered in a subsequent paper.

A set of functions \( F = \{ F_a(x_a, \phi^e, \phi^{e^c}_a, \phi^{e^d}_{\alpha \beta} \} \) \( a, e = 1, 2, \ldots, n \) will be termed of class \( \mathcal{C}^m \) in a region \( R \) of the variables \( x_a, \phi^e, \phi^{e^c}_a, \phi^{e^d}_{\alpha \beta} \) when all of its elements \( F_a \) possess continuous partial derivatives with respect to all its variables up to and including the order \( m \) in every bounded domain contained in \( R \). Here the region \( R \) is the Kronecker product \( R_{x_a} \otimes R_{\phi^e} \otimes R_{\phi^{e^c}_a} \otimes R_{\phi^{e^d}_{\alpha \beta}} \). Partial derivatives of \( F_a \) with respect to the Minkowski coordinates will be denoted with

\[
\partial_a F_a = \frac{\partial F_a}{\partial x^a}, \quad \partial_a \partial_c F_a = \frac{\partial^2 F_a}{\partial x^a \partial x^c}, \quad \text{etc.,}
\]

\[
\partial^a F_a = \frac{\partial F_a}{\partial x^a}, \quad \partial_a \partial_c F_a = \frac{\partial^2 F_a}{\partial x^a \partial x^c}, \quad \text{etc.,}
\]

(2.3)

while for total derivatives we shall use the symbol

\[
d_a F_a = \left\{ \partial_a + \phi^{e^c}_a \frac{\partial}{\partial \phi^e} + \phi^{e^d}_{\alpha \beta} \frac{\partial}{\partial \phi^{e^d}_{\alpha \beta}} + \phi^{e^d}_{\alpha \beta} \frac{\partial}{\partial \phi^{e^d}_{\alpha \beta}} \right\} F_a
\]

\[
= \left\{ \partial_a + \phi^{e^c}_a \frac{\partial}{\partial \phi^e} + \phi^{e^d}_{\alpha \beta} \frac{\partial}{\partial \phi^{e^d}_{\alpha \beta}} + \phi^{e^d}_{\alpha \beta} \frac{\partial}{\partial \phi^{e^d}_{\alpha \beta}} \right\} F_a,
\]

(2.4)

\[
d^a F_a = \left\{ \partial^a + \phi^{e^c}_a \frac{\partial}{\partial \phi^e} \right\} \left\{ \partial^a + \phi^{e^d}_{\alpha \beta} \frac{\partial}{\partial \phi^{e^d}_{\alpha \beta}} \right\} \left\{ \partial^a + \phi^{e^d}_{\alpha \beta} \frac{\partial}{\partial \phi^{e^d}_{\alpha \beta}} \right\} F_a,
\]

and similarly for the case of total derivatives of higher order.

Throughout this paper, unless otherwise stated, we shall tacitly assume that all considered functions \( F_a(x_a, \phi^e, \phi^{e^c}_a, \phi^{e^d}_{\alpha \beta}) \) transform covariantly under the Lorentz group. We shall, however, preserve for completeness a possible explicit dependence on the coordinates.

3. Field Equations

We shall initially be concerned with (covariant) systems of \( n \) second-order partial differential equations of the type

\[
F_a(x_a, \phi^e, \phi^{e^c}_a, \phi^{e^d}_{\alpha \beta}) = 0, \quad a = 1, 2, \ldots, n,
\]

(3.1)

which are not necessarily linear in any of their variables \( x_a, \phi^e, \phi^{e^c}_a \), and \( \phi^{e^d}_{\alpha \beta} \). We shall often refer to Eqs. (3.1) as the nonlinear form of the field equations. For reasons which will be self-evident later on, we shall only consider systems (3.1)
whose functions $F_a$ are of at least class $C^2$ in a region $R_{NL}$ of their variables. The 
functional determinant of Eqs. (3.1) is given by
\[ d_{NL} = d_{NL}(R_{NL}) = | \frac{\partial F_a}{\partial \phi^b_{\mu \nu}} | = | d_{ab}^{\mu \nu} |, \]  
(3.2)
and its elements $d_{ab}^{\mu \nu}$ are also defined in $R_{NL}$. The most significant possibilities occur when the determinant $d_{NL}$ is either identically null everywhere in $R_{NL}$ or is not.

In the former (latter) case, by analogy with a terminology often used in the corresponding Newtonian cases [14], we shall say that system (3.1) is regular (degenerate). Notice that the regularity of a system does not exclude the existence of isolated zeros of its functional determinant [28]. If the rank of the functional matrix is zero, then system (3.1) reduces to a system of first-order partial differential equations. In this case we shall term system (3.1) totally degenerate. The analysis of this paper will be restricted to systems (3.1) which are not only of at least class $C^2$ in a region $R_{NL}$ of their variables, but also regular everywhere in it. Such systems will be indicated with the symbol
\[ (F_a)^{\mu \nu} = 0. \]  
(3.3)

As is well known, the Lagrange equations for continuous systems are always linear in the second-order partial derivatives $\phi^{\mu \nu}$. Therefore, one of the most significant subclasses of systems (3.1) can be written
\[ F_a = A_{ab}^{\mu \nu}(x_\alpha, \phi^a, \dot{\phi}^a) \phi^{\mu \nu} + B_a(x_\alpha, \phi^a, \dot{\phi}^a) = 0, \]  
\[ a, b, c = 1, 2, \ldots, n, \quad \mu, \nu, \alpha = 0, 1, 2, 3. \]  
(3.4)
Notice that the system is not necessarily linear in $x_\alpha, \phi^a, \dot{\phi}^a$ and/or $\ddot{\phi}^a$. We shall refer to Eqs. (3.4) as the quasi-linear [29] form of the field equations.

The continuity properties of the functions $F_a$ can now be assumed in a region $R_{QL}$ of the variables $x_\alpha, \phi^a, \dot{\phi}^a$ only. The functional determinant of Eqs. (3.4) is now $d_{QL} = | A_{ab}^{\mu \nu}(R_{QL}) |$.

A point of particular significance for our analysis is that the terms $A_{ab}^{\mu \nu}$ of Eqs. (3.4) can always be assumed to be symmetrical in the $(\mu, \nu)$ indices, i.e.,
\[ A_{ab}^{\mu \nu} = A_{ab}^{\nu \mu}. \]  
(3.5)
This is due to the fact that these indices are contracted with the totally symmetric derivatives $\phi^{\mu \nu} = \partial_\mu \phi^\nu = \phi^\nu_{\mu \nu}$. And indeed, if the terms $A_{ab}^{\mu \nu}$ do not satisfy such properties, they can always be written $A_{ab}^{\mu \nu} = \frac{1}{2} (A_{ab}^{\mu \nu} + A_{ab}^{\nu \mu}) - \frac{1}{2} (A_{ab}^{\mu \nu} - A_{ab}^{\nu \mu})$.

But the contraction of the antisymmetric parts with the symmetric terms $\phi^{\mu \nu}$ is null. Thus, properties (3.5) always hold up to redefinition.

Throughout our analysis we shall always assume properties (3.5).
System (3.4) will be again termed regular (degenerate) in $R_{QL}$ when determinant $|A^a_{ab}|$ is everywhere non-null (null) in $\tilde{R}_{QL}$. Similarly, we shall say that system (3.4) is totally degenerate when $A^a_{ab} = 0$ for all values of the indices, i.e., which case it reduces to the generally nonlinear system of first-order equations $B_a = 0$. In line with assumptions (3.3) we shall consider only systems (3.4) which are of at least class $\mathcal{C}^2$ and regular in $R_{QL}$, i.e., systems of the type

$$\left(A^a_{ab} \phi^b_{-1} + B_a\right)^2 = 0. \quad (3.6)$$

The almost totality of free or interacting tensorial field equations nowadays considered constitutes the following subclass of Eqs. (3.4):

$$F_a = A^a_{ab} \phi^b_{-1} + B_a = g^{uv} \phi^u_{-1} - f_a(x_a, \phi^c, \phi^{c_i}) = 0, \quad (3.7)$$

namely, it can be obtained from Eqs. (3.4) through the particularization

$$A^a_{0} = \delta^a_b \otimes g^{uv}, \quad B_a = -f_a. \quad (3.8)$$

This is the case, for instance, for the equations of the electromagnetic potential, i.e., $\square A_a = 0$, or the complex scalar fields in interaction with the electromagnetic field; etc. Equations of type (3.7) are called, in the theory of partial differential equations the canonical form [29] of system (3.4), and the transition from Eqs. (3.4) to (3.8) is called, the reduction of the general quasi-linear form to the canonical form.

This terminology is, however, confusing for our framework, particularly when the Hamiltonian formulation is considered. We shall therefore refer to Eqs. (3.7) as the semilinear form of the equations of motion. The reader should, however, be aware of the fact that what are customarily referred to as semilinear forms in the theory of partial differential equations are expressions of the type

$$g(x_n)^{uv} \phi^u_{-1} - f_n(x_n, \phi^c, \phi^{c_i}) = 0. \quad (3.9)$$

namely, when the coefficients $A^{uv}_{ab} = \delta^a_b \otimes g^{uv}(x_n)$ of the quasi-linear form depend on the coordinate $x_n$ only [29].

Nevertheless, equations of type (3.9) appear in a natural way when considering field theory in curved spaces. As a matter of fact, Eqs. (3.7) can sometimes be considered as the limit of Eqs. (3.9) to the (flat) Minkowski space. It is in this sense that we shall use the terminology "quasi-linear form" for Eqs. (3.7), too.

Notice that the reduction from the quasi-linear form to the semilinear form is always possible for $A^a_{ab} = A_{ab} \otimes g^{uv}$, $|A_{ab}| \neq 0$. Indeed, in this case the inverse matrix $(A_{ab})^{-1} = (A^{-1})_{ab}$ exists everywhere in $R_{QL}$. Then the implicit functions $f_a$ of Eqs. (3.8) are given by

$$f_a = -A_a^{-1}b_b. \quad (3.10)$$
Notice also that the hyperbolic character of the field equations under consideration is transparently exhibited by the quasi- and semi-linear form. This character will be tacitly assumed for all other types of considered field equations.

Our analysis of field equations in the semilinear form will be restricted to only those systems which are of at least class \( \mathcal{C}^2 \) in a region \( R_{SL} \) of the variables \( x_\alpha, \phi^\beta, \) and \( \phi_{\alpha \beta} \) (this will later on correspond to Lagrangian densities which are of at least class \( \mathcal{C}^2 \) in \( R_{SL} \)), and we shall write

\[
(g^{\mu \nu} \phi_{\alpha \mu} \phi_{\beta \nu} - f_{\alpha \beta}) = 0.
\]

Notice that the condition of regularity is redundant for the semilinear form because the functional determinant \( d_{SL} = |g^{\mu \nu}| \) is everywhere non-null. Therefore, semilinear forms of the field equations are always everywhere regular.

Another type of field equation we shall consider can be written

\[
g^{\mu \nu} \phi_{\alpha \mu} + \alpha_{\alpha \beta}(x_\alpha) \phi_{\beta \mu} + \beta_{\alpha \mu}(x_\alpha) \phi_{\alpha} = 0,
\]

namely, it is linear in \( \phi^\beta, \phi_{\alpha \beta}, \) and \( \phi_{\alpha \mu} \). For this reason we shall refer to it as the linear form of the field equations. Again, the minimal continuity properties will be that all terms \( \alpha_{\alpha \beta} \) and \( \beta_{\alpha \mu} \) are of at least class \( \mathcal{C}^2 \) in a region \( R_{\alpha} \).

4. Equations of Variation

Consider the \((n + 4)\)-dimensional region \( R_{n+4} \) with points \( (\phi^\alpha, x_\alpha), \alpha = 1, 2, \ldots, n, \alpha = 0, 1, 2, 3 \). The equations \( \phi^\alpha = \phi^\alpha(x) \) determine a hypersurface \( R_\alpha \subset R_{n+4} \).

We shall assume that \( \phi^\alpha \in \mathcal{C}^2(R_\alpha) \). Then \( \phi_{\alpha \mu} \) and \( \phi_{\alpha \beta} \) exist and are continuous in \( R_\alpha \). We shall further assume that the matrix \( (\phi_{\alpha \beta}) \) has rank \( n \) and, thus, \( R_\alpha \) has dimension \( n \).

As is customary in the calculus of variations for multiple integrals [23] we now consider an \( \mathcal{C}^2 \)-parameter family of fields \( \Phi(x, w) = (\phi(x, w)) \) with \( \phi^\alpha \in \mathcal{C}^2(R_\alpha) \), where \( w \) is a free parameter such that \( |w| < \epsilon \) (or \( w \in O_\epsilon \)) and \( \phi^\alpha(x, w)|_{w=0} = \phi^\alpha(x) \). This situation can be interpreted by saying that the hypersurface \( R_\alpha \) depends on a free parameter, \( R_\alpha = R_\alpha(w) \), and the \( x \)'s can be regarded as Gaussian coordinates on \( R_\alpha(w) \) [23]. Consider two neighboring hypersurfaces \( R_\alpha(w) \) and \( R_\alpha(0) \). The variation of the fields in the transition from \( R_\alpha(0) \) to \( R_\alpha(w) \) at a fixed value of the coordinates is given by

\[
\delta \phi^\alpha = w \eta^\alpha(x), \quad \eta^\alpha = (\partial \phi^\alpha/\partial w)|_{w=0}, \quad w \in O_\epsilon.
\]

The functions \( \eta^\alpha(x) \) so defined will be termed the variations of the field \( \phi^\alpha(x) \). Clearly such variations possess the same continuity properties of the fields. Under
the assumptions $\phi^\circ \in \mathcal{G}^3(R^3(w))$ we can therefore extend the above procedure and define the variations $\eta_{\mu}^{\varphi}$ and $\eta_{\mu}^{\varphi}$ through the equations

$$
\delta \phi_{\mu}^{\varphi} = \eta_{\mu}^{\varphi}, \quad \eta_{\mu}^{\varphi} = (\partial \phi_{\mu}^{\varphi}/\partial w)|_{w=0},
$$

$$
\delta \phi_{\mu \nu}^{\varphi} = \eta_{\mu \nu}^{\varphi}, \quad \eta_{\mu \nu}^{\varphi} = (\partial \phi_{\mu \nu}^{\varphi}/\partial w)|_{w=0}.
$$

Then, $\eta_{\mu}^{\varphi} \in \mathcal{G}^1$ and $\eta_{\mu \nu}^{\varphi} \in \mathcal{G}^3$.

We shall term the family of all admissible variations of the fields $\phi^\circ(x)$ the set of all variations $\eta^\circ(x)$ which possess the same continuity properties of the $\phi^\circ$s. The above parametric method of the construction of the variations $\eta^\circ(x)$ is introduced to simply indicate the possibility of constructing different elements of the family of admissible variations and, as such, it should not be considered either exhaustive or unique.

We are now equipped to introduce the first tool of central significance for our analysis, namely, the system of equations of variation of a given set of (tensorial) field equations.

Consider the nonlinear form

$$
[f_a(x, w, \phi^\circ, \phi_{\mu}^{\varphi}, \phi_{\mu \nu}^{\varphi})]_{a=1}^A = 0, \quad (4.3)
$$

computed along an $\infty^3$ family of class $\mathcal{G}^2$ fields $\phi^\circ(x, w)$. Then the system in question can be introduced through the equations

$$
M_\alpha(x, w, \eta, \eta_{\mu}^{\varphi}, \eta_{\mu \nu}^{\varphi}) = (dF_\alpha/dw)|_{w=0} = a_{\alpha b}(x) \eta^b + b_{\alpha b}^c(x) \eta_{\mu}^{\varphi c} + c_{ab}^{\mu \nu}(x) \eta_{\mu \nu}^{\varphi} = 0, \quad (4.4)
$$

where all terms

$$
a_{\alpha b} = (\partial F_\alpha/\partial \phi^\circ)|_{w=0}, \quad b_{\alpha b}^c = (\partial F_\alpha/\partial \phi_{\mu}^{\varphi c})|_{w=0}, \quad c_{ab}^{\mu \nu} = (\partial F_\alpha/\partial \phi_{\mu \nu}^{\varphi})
$$

now possess only a dependence on the coordinates $x_b$ because the functions $F_\alpha$ are computed along assigned fields $\phi^\circ(x, w)$. For simplicity of notation we shall denote the forms (4.4) with the symbol $M_\alpha(\eta)$.

A comparative analysis of systems (4.3) and (4.4) indicates that the system of equations of variation always constitutes a linear (homogeneous) system of partial differential equations in $\eta^b, \eta_{\mu}^{\varphi}, \eta_{\mu \nu}^{\varphi}$, irrespective of whether the original system is linear or not.

The equations of variation for other forms of the field equations (Section 3) can be constructed accordingly.
5. Adjoint Systems of Variations

Consider the differential form $M_a(\eta)$ of variations (4.4) and let $\tau$ be the family of all admissible variations. A system $\bar{M}_a(\bar{\eta})$ with $\bar{\eta} \in \tau$, $\bar{\eta} \neq \eta$ is termed the adjoint system of variations $M_a(\eta)$ when there exists a current density $J^a(x, \eta, \eta^a_a, \bar{\eta}^a, \bar{\eta}^a_a)$ such that

$$\bar{\eta}^a M_a(\eta) - \eta^a \bar{M}_a(\bar{\eta}) = \partial_a J^u$$

(5.1)

for all admissible variations.

Apparently, condition (5.1) for the case of only one independent variable $x = t$ has been introduced for the first time by Lagrange [30]. We shall therefore term it the Lagrange identity.

We shall term system $\bar{M}_a(\bar{\eta})$ a quasi-adjoint system of variations $M_a(\eta)$ when the following integral version of Eqs. (5.1) holds:

$$\int_{R_a} d^4x \left[ \bar{\eta}^a M_a(\eta) - \eta^a \bar{M}_a(\bar{\eta}) \right] = \int_{\partial R_a} d\sigma_a(x) \mathcal{J}^u.$$

(5.2)

The above expression is the Green formula of the theory of partial differential equations [29].

It is evident that conditions (5.1) and (5.2) are not equivalent. Indeed, one can have (e.g., for nonlocal theories) systems $\bar{M}_a(\bar{\eta})$ which do not satisfy the Lagrange condition, but they are such that

$$\bar{\eta}^a M_a(\eta) - \eta^a \bar{M}_a(\bar{\eta}) = \partial_a J^u + D,$$

(5.3)

where the additive density $D$ is such that [31]

$$\int_{R_a} d^4x \left( \partial_a J^u + D \right) = \int_{\partial R_a} d\sigma_a(x) \mathcal{J}^u.$$

(5.4)

In this case $\bar{M}_a(\bar{\eta})$ is not the adjoint system of $M_a$ according to our definition. However, if Eqs. (5.3) and (5.4) hold with $D \neq 0$, then the system $\bar{M}_a(\bar{\eta})$ is quasi-adjoint.

This paper's analysis will be based on the use of the concept of adjoint systems with related Lagrange identities, and therefore we shall devote only marginal attention at this time to the concept of quasi-adjoint systems and related Green identities.

To identify the structure of the adjoint system $\bar{M}_a$ we now write

$$\bar{\eta}^a M_a = \eta^b \bar{\eta}^a \delta_{ab} - \partial_a (\bar{\eta}^b \delta_{ab}) + \partial_a \partial_a (\bar{\eta}^b \delta_{ab})$$

$$+ \partial_a (\bar{\eta}^b \delta_{ab} \bar{\eta}^a) + \bar{\eta}^a \delta_{ab} \partial_a \bar{\eta}^b - \partial_a (\bar{\eta}^b \delta_{ab}) \bar{\eta}^b,$$

(5.5)
Thus, an explicit form of the adjoint system is
\[ \tilde{M}_a(\eta) = \tilde{\eta}^a a_{ab} - \partial_a(\tilde{\eta}^b b_{ab}) + \partial_a(\tilde{\eta}^b c_{ab}^c), \tag{5.6} \]

while the current density of the Lagrange identity is
\[ J^a(\eta, \tilde{\eta}) = \tilde{\eta}^a b_{av}\eta^b + \tilde{\eta}^a c_{av}\eta^b, \tag{5.7} \]

It is possible to prove that form (5.6) of the adjoint system is indeed unique under the assumed continuity and regularity conditions. Suppose that there are two adjoints \( \tilde{M}_a \) and \( \tilde{M}_a' \) and, therefore, two currents \( J^a \) and \( J'^a \) for the same system \( M_a \). By subtracting the corresponding identities (5.1) and by integrating we reach the equation
\[ \int_{R_a} d^4x \eta^a (\tilde{M}_a - \tilde{M}_a') = \int_{\partial R_a} da_a(\chi)(J^a - J'^a). \tag{5.8} \]

But this expression must be independent of points in the interior of the \((\eta, \tilde{\eta})\) space. This can be so iff \( \tilde{M}_a = \tilde{M}_a' \).

Notice that the quasi-adjoint system is not necessarily unique. This indicates another reason for preferring the Lagrange over the Green identity.

6. CONDITIONS OF SELF-ADJOINTNESS

A system of differential forms \( M_a \) is termed self-adjoint when it coincides with the adjoint system \( \tilde{M}_a \) for all admissible variations, i.e.,
\[ M_a(\eta) = \tilde{M}_a(\eta) \quad \text{for all } \eta \in \tau. \tag{6.1} \]

The conditions of self-adjointness can be obtained by simply imposing the identity between forms (4.4) and (5.6), i.e.,
\[ a_{ab} \eta^b + b_{ab} \eta^b b_{ab} + c_{ab} \eta^b c_{ab}^c = \eta^b a_{ab} - \partial_a(\tilde{\eta}^b b_{ba}) + \partial_a(\tilde{\eta}^b c_{ba}^c). \tag{6.2} \]

In this way we reach the conditions which we term the \textit{conditions of self-adjointness of the equations of variation}:

\[ c_{ab}^{av} = c_{ba}^{av} = c_{ab}^{va} = c_{ba}^{va}, \tag{6.3a} \]
\[ b_{ab}^{av} + b_{ba}^{av} = \partial_a c_{ba}^{av} = \partial_a c_{ba}^{va} = 2\partial_a c_{ba}^{av}, \tag{6.3b} \]
\[ a_{ab} - a_{ba} = \partial_a c_{ba}^{av} = \partial_a c_{ba}^{va}, \tag{6.3c} \]
where the last two identities of Eqs. (6.3a) hold under the same redefinition as for Eqs. (3.5).

We must inspect the possible conservation of the current \( J^\mu \) of the Lagrange identity (5.1) under the condition of self-adjointness. The term \( \partial_\mu J^\mu \) in view of Eqs. (5.7) can be written

\[
\partial_\mu J^\mu = \eta^{\mu \nu} [\eta_{\mu \nu} + c_{\mu \nu} + \eta^{\mu \nu} \eta^{\nu \rho} + (\partial_\mu \eta_{\rho \eta} - (\partial_\mu \rho_{\eta \eta} \eta^{\nu \eta} \eta^{\nu \rho}) \eta^{\nu \rho} \\
+ \eta_{\mu \nu} b_{\eta \eta} \eta^{\nu \rho} - (\partial_\mu \rho_{\eta \eta} \eta^{\nu \rho} - (\partial_\mu \rho_{\eta \eta} \eta^{\nu \rho} \eta^{\nu \rho} \eta^{\nu \rho} \eta^{\nu \rho}) \eta^{\nu \rho}.
\]

Suppose that one studies the possible self-adjointness of the system of equations \( M_a = 0 \) rather than of the differential forms \( M_a \). Then the admissible variations \( \eta \) and \( \eta \) are restricted to the solutions \( \eta_0 \) and \( \eta_0 \) of the system of equations of variation and its adjoint system, respectively. By using Eqs. (4.4) we first write

\[
\partial_\mu J^\mu \bigg|_{\theta = \theta_0} = [\eta^{\mu \nu} (-a_{\mu \nu} + \partial_\mu c_{\nu} - \partial_\nu c_{\mu})] \\
+ (b_{\mu \nu} - \partial_\mu \rho_{\eta \eta} - \partial_\nu \rho_{\eta \eta} - \eta_{\mu \nu} c_{\eta \eta}) \eta_0.
\]

and by using the conditions of self-adjointness (6.3) we finally obtain the conservation law

\[
\partial_\mu J^\mu \bigg|_{\theta = \theta_0} = -(a_{\mu \nu} \eta_0^{\mu \nu} + b_{\mu \nu} \eta_0^{\mu \nu} + c_{\mu \nu} \eta_0^{\mu \nu} \eta_0^{\nu \rho}) \eta_0 = 0.
\]

As an alternative to definition (6.1) we can therefore say that a system of differential equations \( M_a = 0 \) is termed self-adjoint when the current density \( J^\mu \) of the Lagrange identity (5.1) is conserved along the solutions of the system, i.e.,

\[
\partial_\mu J^\mu(\eta, \eta)_{\theta = \theta_0} = 0.
\]

Notice that definitions (6.1) and (6.7) are equivalent. Indeed, all conditions of self-adjointness (6.3) enter into condition (6.7). Let us also recall that, under our assumptions, Eqs. (6.7) are the necessary and sufficient conditions for the surface independence [32]

\[
[\delta \psi(x)] \int_{\sigma = \partial_\theta} \text{space-like} \quad d\sigma(x) J^\mu(\eta_0, \eta_0) = 0.
\]

Therefore, conservation law (6.8) is also equivalent to Eq. (6.7).

A system of field equations is termed self-adjoint when its system of equations of variation is self-adjoint.

We shall now give the necessary and sufficient conditions of self-adjointness for the various forms of field equations considered in Section 3.
First of all, by using Eqs. (6.3) and (4.5) together with the uniqueness of the adjoint system we have

**Theorem 6.1.** Necessary and sufficient condition for class \( \mathcal{C}^a \), regular, nonlinear, tensorial field equations

\[
[F_a(x_a, \phi^i, \phi^{a_i}, \phi^{a_i a})]_{\pm}^{\pm} = 0, \quad a = 1, 2, ..., n \tag{6.9}
\]

to be self-adjoint in a region \( R_{NL} \) of their variables is that all the following conditions

\[
\frac{\partial F_a}{\partial \phi^{a_i}_{\pm \mu}} = \frac{\partial F_b}{\partial \phi^{a_i}_{\pm \nu}} = \frac{\partial F_a}{\partial \phi^{a_i}_{\pm \nu}} = \frac{\partial F_b}{\partial \phi^{a_i}_{\pm \mu}}; \tag{6.10a}
\]

\[
\frac{\partial F_a}{\partial \phi^{a_{\pm i}}_{\pm \mu}} + \frac{\partial F_b}{\partial \phi^{a_{\pm i}}_{\pm \nu}} = d_i \left( \frac{\partial F_b}{\partial \phi^{a_{\pm i}}_{\pm \nu}} + \frac{\partial F_b}{\partial \phi^{a_{\pm i}}_{\pm \mu}} \right) = 2 d_i \frac{\partial F_b}{\partial \phi^{a_{\pm i}}_{\pm \nu}}, \tag{6.10b}
\]

\[
\frac{\partial F_a}{\partial \phi^{b}_{\pm \mu}} - \frac{\partial F_b}{\partial \phi^{b}_{\pm \nu}} = d_i d_\nu \frac{\partial F_b}{\partial \phi^{a_{\pm i}}_{\pm \nu}} - d_\mu \frac{\partial F_b}{\partial \phi^{a_{\pm i}}_{\pm \mu}} = \frac{1}{2} \left( \frac{\partial F_a}{\partial \phi^{b}_{\pm \mu}} - \frac{\partial F_a}{\partial \phi^{b}_{\pm \nu}} \right), \tag{6.10c}
\]

are satisfied in every bounded domain in the interior of \( R_{NL} \).

Notice that conditions (6.10) imply second-order derivatives. This illustrates the reason for our restriction to systems which are of at least class \( \mathcal{C}^a \).

Equations (6.10) will be referred to here as the conditions of self-adjointness of the nonlinear form of the field equations. When all these conditions hold we shall symbolically write

\[
(F_{a_{\pm}^{\mathcal{C}^a}, R} = 0. \tag{6.11}
\]

When at least one of Eqs. (6.10) is violated we shall say that the nonlinear form is non-self-adjoint and we shall write

\[
(F_{a_{\pm}^{\mathcal{C}^a}, R} = 0. \tag{6.12}
\]

Notice that brackets of the type ( )\( _{SA}^{\mathcal{C}^a, R} \) are a notation and not an operation. Notice also that for the case under consideration, namely, (unconstrained) class \( \mathcal{C}^a \) and regular field equations, to verify the self-adjointness it is sufficient to check identities (6.1) or (6.7) or (6.8) for only one admissible variation or to show that Eqs. (6.10) hold as identities between functions. The reader should be aware of the fact that for field theories with subsidiary constraints this framework is considerably altered because the constraints generally impose restrictions on the class of admissible variations [3]. This aspect, however, will not be considered at this time.
Let us note at this point that the nonlinear form of the field equations, even though it is the most general form for the class of field equations under consideration (i.e., of the second-order type), it ultimately possesses only a formal significance for our program. This is due to the fact, as we shall see better in Section 7, that the largest form of tensorial field equations which can be represented in terms of the Lagrange equations is the quasi-linear form.

The conditions of self-adjointness for the quasi-linear form of the field equations are therefore crucial for our program. It is a matter of simple calculations, which are given for the reader's convenience in Appendix A, to prove

**Theorem 6.2.** Necessary and sufficient conditions for class $\mathcal{G}_2$, regular, Lorentz-covariant, tensorial, quasi-linear systems of field equations

\[
[A_{\alpha \beta}(x, \phi, \phi^\alpha) \phi^{\beta \gamma} + B_{\alpha}(x, \phi, \phi^\alpha)]^{\gamma, \kappa} = 0,
\]

\[A_{\alpha \beta}^{\mu \nu} = A_{\alpha \beta}^{\nu \mu}, \quad (6.13a)\]

\[a, b, c = 1, 2, ..., n, \quad \mu, \nu, \alpha = 0, 1, 2, 3, \quad (6.13b)\]

to be self-adjoint in a region $\mathcal{R}_{OL}$ of their variables are that all the following conditions

\[A_{\alpha \beta}^{\mu \nu} = A_{\alpha \beta}^{\nu \mu} = A_{\alpha \beta}^{\mu \nu}, \quad (6.14a)\]

\[A_{\alpha \beta \gamma}^{\mu \nu} + A_{\alpha \gamma \beta}^{\mu \nu} = A_{\alpha \beta \gamma}^{\nu \mu}, \quad (6.14b)\]

\[A_{\alpha \beta \gamma \delta}^{\mu \nu} = A_{\beta \alpha \gamma \delta}^{\nu \mu}, \quad (6.14c)\]

\[B_{\mu \alpha}^{\nu \beta} + B_{\nu \alpha}^{\mu \beta} = 2(\partial_{\nu} + \phi^{\nu \alpha}(\partial/\partial \phi^\alpha)) A_{\alpha \beta}^{\mu \nu}, \quad (6.14d)\]

\[B_{\alpha}^{\mu \beta} - B_{\mu}^{\alpha \beta} = \frac{1}{2}(\partial_{\alpha} + \phi^{\alpha \gamma}(\partial/\partial \phi^\gamma))(B_{\alpha}^{\nu \beta} - B_{\beta}^{\nu \alpha}); \quad (6.14e)\]

\[A_{\alpha \beta \gamma}^{\mu \nu} = (\partial A_{\alpha \beta}^{\mu \nu} / \partial \phi^\alpha), \quad B_{\alpha}^{\beta} = (\partial B_{\alpha}^{\nu} / \partial \phi^\nu), \quad \text{etc.} \quad (6.14f)\]

\[A_{\alpha \beta}^{\mu \nu} = A_{\alpha \beta}^{\mu \nu} + A_{\alpha \beta}^{\mu \nu}, \quad (6.14g)\]

\[A_{\alpha \beta}^{\mu \nu} = A_{\alpha \beta}^{\mu \nu} + A_{\alpha \beta}^{\mu \nu}, \quad (6.14h)\]

\[a, b, c, d = 1, 2, ..., n, \quad \mu, \nu, \alpha, \beta = 0, 1, 2, 3, \quad (6.14)\]

are verified in every bounded domain in the interior of $\mathcal{R}_{OL}$.
Notice that the horizontal bars in Eqs. (6.14) denote symmetrization of the indicated indices as expressed by Eqs. (6.14g) and (6.14h). The symbolic derivative notation, as in Eqs. (6.14f) is here introduced for notational convenience. However, for the sake of clarity, we shall revert to the conventional notation whenever possible. Notice that Eqs. (6.14) contain partial derivatives up to and including the second order. This indicates the reason why our minimal continuity conditions are that Eqs. (6.13) be of class $C^2$. Notice also that symmetry properties (6.13b) hold under redefinition, as pointed out in Section 3.

We shall term Eqs. (6.14) the **conditions of self-adjointness of the quasi-linear form of field equations**. Quasi-linear systems will be termed self-adjoint when all conditions (6.14) hold, and we shall then symbolically write

$$ (A^a_{ab} \phi^b_{\alpha} + B_{ab} \phi^a) = 0. \quad (6.15) $$

If at least one of conditions (6.14) is violated we shall term the system **non-self-adjoint** and write

$$ (A^a_{ab} \phi^b_{\alpha} + B_{ab} \phi^a) = 0. \quad (6.16) $$

As indicated earlier, the almost totality of field equations considered nowadays is of the semilinear rather than of the quasi-linear type. It is therefore useful for our analysis to work out the conditions of self-adjointness specifically for the semilinear form.

It is again a matter of simple calculations (given in Appendix B) to prove

**Theorem 6.3.** Necessary and sufficient conditions for class $C^1$, semilinear, tensorial field equations

$$ [\epsilon^{abc} \phi_{\alpha} + f_a(x_\alpha, \phi^n, \phi^{\alpha})] = 0 \quad (6.17) $$

to be self-adjoint in a region $R_{ab}$ of their variables are that the system is linear in the partial derivatives $\phi_{\alpha}$, i.e., it is of the type

$$ [\epsilon^{abc} \phi_{\alpha} + \rho_{ab}(x_\alpha, \phi^n) \phi^{b\alpha} - \sigma_a(x_\alpha, \phi^n)] \phi^{\alpha} = 0, \quad (6.18) $$

and all the conditions of self-adjointness

$$ \rho_{ab} + \rho_{ba} = 0, \quad (6.19a) $$

$$ (\partial \rho^{\alpha}_a / \partial \phi^b) + (\partial \rho^{\alpha}_b / \partial \phi^a) = 0, \quad (6.19b) $$

$$ \partial_a \rho^{\alpha}_a = (\partial \sigma_a / \partial \phi^b) - (\partial \sigma / \partial \phi^a), \quad (6.19c) $$

$$ a, b, c = 1, 2, \ldots, n, \quad \mu = 0, 1, 2, 3, \ldots. \quad (6.19) $$
are everywhere satisfied in every bounded domain in the interior of the subregion $R'^{c}_{St}$ of $R_{St}$ with points $(x_{a}, \phi^{\mu})$.

Notice that conditions (6.19) imply only first-order partial derivatives and therefore the minimal continuity condition is that the semilinear form be of class $C^{1}$ in $R'^{c}_{St}$. Notice also that the derivatives of Eq. (6.19c) are partial. Therefore, if the terms $\rho_{\mu}^{a}$ do not depend explicitly on the coordinates $x_{a}$, i.e., Eqs. (6.18) are of the type

\[ [g^{\mu\nu}\phi^{i}_{a} \phi^{j}_{\mu} - \rho_{\mu}^{a}(\phi^{\nu}) \phi^{i}_{a} - \sigma_{a}(x_{a}, \phi^{\mu})]\phi^{\nu} = 0, \tag{6.20} \]

then the conditions of self-adjointness become

\[ \rho_{\mu}^{a} + \rho_{\mu}^{a} = 0, \tag{6.21a} \]

\[ (\partial \rho_{\mu}^{a}/\partial \phi^{b}) + (\partial \rho_{\mu}^{a}/\partial \phi^{b}) + (\partial \rho_{\mu}^{a}/\partial \phi^{b}) = 0, \tag{6.21b} \]

\[ (\partial c_{a}/\partial \phi^{b}) - (\partial c_{a}/\partial \phi^{b}) = 0, \tag{6.21c} \]

\[ a, b, c = 1, 2, \ldots, n, \quad \mu = 0, 1, 2, 3. \]

When conditions (6.19) hold, the semilinear form (6.18) can be further specialized. Indeed, antisymmetry condition (6.19a) combined with the recursive condition (6.19b) implies that the factor coefficients $\rho_{\mu}^{a}$ of the derivative terms $\phi^{\mu}_{a}$ are the curl of some function, say $\Gamma_{a}(x_{a}, \phi^{b})$, i.e.,

\[ \rho_{\mu}^{a}(x_{a}, \phi^{b}) = (\partial \Gamma_{a}/\partial \phi^{b}) - (\partial \Gamma_{a}/\partial \phi^{b}). \tag{6.22} \]

Suppose also that the additive term $\sigma_{a}$ admits the decomposition

\[ \sigma_{a}(x_{a}, \phi^{b}) = -m_{a} \phi_{a} + A_{a}(x_{a}, \phi^{b}), \tag{6.23} \]

where the $m$'s are constants and there is no summation on the indices of the term $m_{a} \phi_{a}$. Then Eqs. (6.18) can be written in the form

\[ (\Box + m^{2}_{a}) \phi_{a} = \left( \frac{\partial \Gamma_{a}(x_{a}, \phi^{b})}{\partial \phi^{b}} - \frac{\partial \Gamma_{a}(x_{a}, \phi^{b})}{\partial \phi^{b}} \right) \phi^{b}_{a} + A_{a}(x_{a}, \phi^{b}), \tag{6.24} \]

which we term the conventional form of the field equations. Notice that conditions (6.19a) and (6.19b) are identically verified for this form and, as such, they can be ignored.

We are now equipped to study the self-adjointness or non-self-adjointness of some of the known cases of free or interacting tensorial fields.
COROLLARY 6.3A. The equations for free tensorial fields in the conventional form

\[(\square + m^2_{\alpha\alpha}) \phi_a = 0, \quad a = 1, 2, \ldots, n\]  \hspace{1cm} (6.25)

are always self-adjoint.

This is the case for instance, for the electromagnetic potential \(\{\phi_a\} = \{A_a\}\), \(m_a = 0\), the real scalar field \(\phi = \varphi\), the complex scalar field \(\{\phi_1, \phi_2\} = \{\varphi, \bar{\varphi}\}\), \(m_1 = m_2\), or the complex vector field \(\{\phi_3\} = \{\psi^\mu, \bar{\psi}^\mu\}\), \(m_3 = m_4\) in \(\mu = 0, 1, 2, 3\).

The "conventional" form of Eqs. (6.25) must be stressed. Indeed, if such equations are written, for instance, in the "unconventional" form

\[(1/\phi^a)(\Box \phi_a) + m^2_{\alpha\alpha} = 0\]  \hspace{1cm} (6.26)

(no summation on repeated indices), then they are no longer self-adjoint. Indeed, the transition from Eqs. (6.25) to Eqs. (6.26) is in actuality a transition from the semilinear to the quasi-linear form. Therefore, the condition of self-adjointness (6.14) rather than (6.19) must now be used. By putting \(A^\alpha_{\nu} = \delta^\alpha_{\nu} \otimes \phi^\nu/\phi_a\) and \(B_a = m^2_{\alpha\alpha}\), the only surviving condition originating from Eqs. (6.14) is given by

\[2(\partial_a + \phi^a (\partial/\partial \phi^a)) A^\alpha_{\nu} = 2(\partial_a (\phi^a)^{-1} - \phi^a_a (\phi^a)^{-3}) = 0,\]

and it is clearly violated by the solutions \(\phi_a(x)\) of the field equations (6.25).

Notice the insensitivity of the self-adjointness of Eqs. (6.25) for the behavior of the fields under discrete transformations. Thus, Eqs. (6.25) for \(\{\phi_a\} = \{\varphi, \bar{\varphi}\}\) are self-adjoint irrespective of whether the represented field is scalar or pseudoscalar. Similarly for other cases. The case of internal symmetries or supersymmetries, however, demands a specific treatment and it will not be considered at this time.

COROLLARY 6.3B. Necessary and sufficient condition for the equations of interacting tensorial fields without derivative couplings in the conventional form

\[(\square + m^2_{\alpha\alpha}) \phi_a = A_a(x_a, \phi^a), \quad a = 1, 2, \ldots, n\]  \hspace{1cm} (6.27)

to be self-adjoint in a region \(R_{\text{SL}}\) of points \((x_a; \phi^a)\) is that all the following conditions

\[(\partial A_a/\partial \phi_b) - (\partial A_b/\partial \phi_a) = 0, \quad a, b = 1, 2, \ldots, n\]  \hspace{1cm} (6.28)

are verified in every bounded domain in the interior of \(R_{\text{SL}}\).

In particular, self-coupled models of the type

\[(\square + m^2) \phi = \Lambda(\phi),\]  \hspace{1cm} (6.29)
where $\Lambda(\phi)$ is any class of function of its argument are always self-adjoint. This is the case, for instance, of the $\phi^4$ theories with spontaneous breaking of the $\phi \rightarrow -\phi$ symmetry [33]

$$(\Box + m^2) \phi = (\partial \Sigma/\partial \phi), \Sigma = (m^4/2g^2) + (g^2/2) \phi^4.$$  

(6.30)

But, again, if the field equation is written in some "unconventional" form they are not necessarily self-adjoint.

Notice that the conditions of self-adjointness (6.28) are insensitive to a possible explicit dependence of the $\Lambda$ terms in the coordinates.

**Corollary 6.3C.** Necessary and sufficient conditions for the equations of interacting tensorial fields with derivative couplings in the conventional form

$$(\Box + m^2_{\alpha}) \phi_{\alpha} = j_{\alpha}(x_\alpha, \phi^e, \phi^{'e\alpha})$$  

(6.31)

to be self-adjoint in a region $R_{\text{SL}}$ of points $(x_\alpha, \phi^e, \phi^{'e\alpha})$ are that the $j$ terms possess a structure of the type

$$j_{\alpha} = \left[ \frac{\partial \Gamma_{\alpha}^{u}(x_\alpha, \phi^e)}{\partial \phi^u} - \frac{\partial \Gamma_{\alpha}^{u}(x_\alpha, \phi^e)}{\partial \phi^v} \right] \phi^v_{\alpha} + A_{\alpha}(x_\alpha, \phi^e),$$  

(6.32)

and all the following conditions

$$\partial_{\alpha} \left( \frac{\partial \Gamma_{\alpha}^{u}}{\partial \phi^u} - \frac{\partial \Gamma_{\alpha}^{v}}{\partial \phi^v} \right) = \frac{\partial A_{\alpha}}{\partial \phi^u} - \frac{\partial A_{\beta}}{\partial \phi^v}$$  

(6.33)

are verified in every bounded domain in the interior of the subregion $R'_{\text{SL}} \subset R_{\text{SL}}$ with points $(x_\alpha, \phi^e)$.

Thus, when derivative couplings $\phi^{v\mu}$ occur, some necessary (but not sufficient) conditions to satisfy the requirement of self-adjointness are that they must occur linearly and their factor term must be the curl of some functions $\Gamma_{\alpha}^{u}$.

For instance, the field equations

$$(\Box + m^2) \varphi = ia^{\mu} \varphi^{i}_{\mu},$$  

(6.34)

$$(\Box + m^2) \bar{\varphi} = -ia^{\mu} \bar{\varphi}^{i}_{\mu}$$

for some constant four-vector $a^{\mu}$ are self-adjoint because there exist the functions

$$\Gamma_{\alpha}^{u} = \Gamma_{\beta}^{v} = (i/2) a^{\mu}(\bar{\varphi} - \varphi)$$  

(6.35)
such that

\[ \frac{\partial \Gamma_{\nu}}{\partial \phi} = \frac{\partial \Gamma_{\nu}}{\partial \phi} - \frac{\partial \Gamma_{\nu}^*}{\partial \phi^*}, \quad -i \alpha^u = \frac{\partial \Gamma_{\nu}^*}{\partial \phi} - \frac{\partial \Gamma_{\nu}}{\partial \phi}, \] (6.36)

and Eqs. (6.33) hold.

The reader should be aware of the fact that the conditions of self-adjointness (6.14) for the quasi-linear form do not demand linearity of the derivative couplings.

A most important example of semilinear systems is constituted by the complex scalar field in interaction with the electromagnetic field with the conventional form of the field equations

\[ \Box A_{\mu} = i \epsilon \left[ (\bar{\psi} \gamma_{\mu} + i e A_{\mu} \bar{\psi}) \phi - \bar{\psi} (\gamma_{\mu} - i e A_{\mu} \psi) \right], \]
\[ (\Box + m^2) \phi = e^2 A_{\mu} A^\mu \phi + 2 i e A^\mu \phi_{,\mu}, \]
\[ (\Box + m^2) \bar{\psi} = e^2 A_{\mu} A^\mu \bar{\psi} - 2 i e A^\mu \bar{\psi}_{,\mu}. \] (6.37)

It is easy to see that this system is not self-adjoint, because conditions (6.33) are generally violated despite the linearity of the derivative couplings (see also Appendix C). This case of “self-adjointness breaking” will play a significant role in our analysis.

Table I summarizes our findings.

We now briefly discuss a possible interplay between the quasi-linear and the semilinear forms. Here a digression into Newton’s equations in configuration space may be instructive. The Newtonian equivalent of the semilinear form (6.17) is the system of second-order ordinary differential equations

\[ \ddot{q}_k - f_k(t, q, \dot{q}) = 0, \quad k = 1, 2, \ldots, n. \] (6.38)

An example is given by the system of coupled, linearly damped, and forced oscillators

\[ \ddot{q}_k + b_k(t) \dot{q}_k + a_k(t) q_k - g_k(t) = 0. \] (6.39)

Similarly, the Newtonian equivalent of the quasi-linear form (6.13) is given by the fundamental form of the equations of motion

\[ A_{k\ell}(t, q, \dot{q}) \dot{q}_k + B_k(t, q, \dot{q}) = 0, \]
\[ A_{k\ell}, B_k \in \mathbb{R}^n, \quad |A_{ij}| \neq 0. \] (6.40a, 6.40b)

A significant example is given by the broader system of coupled oscillators

\[ c_{k\ell}(t) \dot{q}_k + b_k(t) \dot{q}_k + a_k(t) q_k - g_k(t) = 0, \]
\[ |c_{ij}| \neq 0. \] (6.41)

</table>

* The equations of variation are computed by using Eqs. (4.4), and the adjoint system is computed by using Eqs. (5.6). Notice that all equations of variation and adjoint systems are linear. For instance, case 3, which is a self-coupled nonlinear model, possesses a linear equation of variation. This system is also self-adjoint. The subsequent example 4 constitutes a simple example of “self-adjointness-breaking” due to the presence of nonlinear derivative couplings. However, system 6, which does possess linear derivative couplings, is also non-self-adjoint. The most conspicuous example of “self-adjointness-breaking” is constituted by example 7, namely, by the complex scalar field in interaction with the electromagnetic field. Notice the modification of the coupling terms from the field equations to the equations of variation.
Clearly, system (6.41) is more general than system (6.29) in view of the acceleration couplings which occur whenever \( c_{kl} \neq N_{kl} \), \( N_k = \text{const.} \).

However, system (6.41) can be reduced to a system of type (6.39) when it is regular, i.e., \( \det (c_{kl}) \neq 0 \). Indeed, we can trivially write the system equivalent to (6.41),

\[
\begin{align*}
\ddot{q}_k + b'_{kl}(t) \dot{q}_l + a'_{kl}(t) q_l - g'_{kl}(t) &= 0, \\
b'_{kl} &= c_{kl}^{-1} b_{kl}, & a'_{kl} &= c_{kl}^{-1} a_{kl}, \\
g'_{kl} &= c_{kl}^{-1} g_{kl}.
\end{align*}
\]

(6.42)

More generally, when the conditions of the implicit function theorem apply, Eqs. (6.40) can be reduced, at least locally, to Eqs. (6.38) with the implicit functions given, trivially, by

\[
f_k = -A_k b_k.
\]

(6.43)

We can thus say that, under our continuity and regularity assumptions (6.40b), forms (6.38) and (6.40) are equivalent in the sense that each of these forms can be transformed into the other, and vice versa, through equivalence transforms.

As we have shown in [3], this equivalence of forms (6.38) and (6.40), even though it is trivial within the framework of ordinary differential equations, is not trivial for the problem of the existence of a Lagrangian, as well as for that of equivalent Lagrangians. This is due to the fact that the transition from Eqs. (6.38) to (6.40), and vice versa, does not in general preserve the self-adjointness or non-self-adjointness. Therefore, if a Lagrangian exists for one of these forms it does not necessarily exist for the other. Furthermore, there may exist different (but equivalent) self-adjoint forms, in which case there exist different Lagrangians all representing the same system.

The corresponding situation in field theory is considerably (although not entirely) equivalent to the above Newtonian framework. First of all, one can always transform the semilinear into a quasi-linear form through an equivalence mapping of the type

\[
\{h_k(x, \phi^e, \phi_s)| g_{kl} \phi^e_k \phi^e_l - f_k(x, \phi^e, \phi_s)\}^{g_1, g_2, R} = [A_k(x, \phi^e, \phi_s) \phi^e_k \phi^e_l + B_k(x, \phi^e, \phi_s)\}^{g_1, g_2, R} = 0.
\]

(6.44)

This, in essence, corresponds to the introduction of “acceleration couplings” similar in concept to those of system (6.41) in a way which preserves the equivalence of the old and the new systems.

It is then a matter of simple inspection to see that if the original semilinear system is self-adjoint (or non-self-adjoint), this is not necessarily the case for the
equivalent quasi-linear form, and vice versa. This property will have significant implications for our analysis.

The inverse transition (from a quasi-linear to a semilinear form), however, does not appear to necessarily follow the Newtonian pattern. This is due to the fact that the terms $A_{ab}^{\mu}$ do not generally admit the factorization

$$
A_{ab}^{\mu} = A_{ab} \otimes g^{\mu},
$$

and therefore the inverse reduction of (6.44) is not in general trivial. For instance, when $n = 5$ and $\{\phi_{\alpha}\} = \{\varphi, \psi^{\mu}\}$, where $\varphi$ and $\psi^{\mu}$ are scalar and vector fields, respectively, one might conceive coupled equations of the type

$$
\begin{align*}
\varphi &+ m_{\varphi} \varphi + g_{\varphi}(\varphi, \psi^{\mu}) \varphi^{,\mu} = 0, \\
g_{\varphi}(\varphi, \psi^{\mu}) \varphi^{,\mu} + (\Box + m_{\psi}) \psi_{\psi} = 0, \\
(\mathcal{A}_{ab}^{\mu}) &= \left(\begin{array}{c}
(g_{\varphi}(\varphi, \psi^{\mu}) + g_{\psi}(\psi^{\mu}, \varphi)) \\
(g_{\varphi}(\varphi, \psi^{\mu}))
\end{array}\right) \\
\{A, B\} &= AB + BA,
\end{align*}
$$

which reduce to free-field equations at the limit $g_{1}, g_{2} \to 0$. In this case the $(20 \times 20)$ matrix $(\mathcal{A}_{ab}^{\mu})$ does not admit factorization (6.45) and the reduction to a semilinear form is not trivial.

Needless to say, system (6.46), although Lorentz covariant, is not "coupled" according to currently used rules. Nevertheless, the example is significant to illustrate that what we have termed the "quasi-linear form" of the field equations is not necessarily related in a trivial way to the conventional semilinear form and, as such, it might constitute a true generalization of conceivable ways of coupling tensorial fields.

As a final point we want to stress that this quasi-linear form has not been constructed ad hoc. It simply constitutes the most general form of tensorial field equations which can be represented in terms of Lagrange equations.

7. Lagrange Equations

We now consider the conventional Lagrange equations

$$
\mathcal{L}(\phi) = d_{a}(\partial \mathcal{L}/\partial \phi^{a}) - (\partial \mathcal{L}/\partial \phi^{a}) = 0,
$$

$$
a = 1, 2, ..., n, \quad \mu = 0, 1, 2, 3,
$$

where $\mathcal{L} = \mathcal{L}(x_{\mu}, \phi^{a}, \phi^{a})$ is the Lagrangian density customarily defined in a
Equations (7.1) are the Euler equations of the hyperbolic multiple integral variational problem [34]

$$A(\phi) = \int_{R_e} d^4x \mathcal{L}(x_\nu, \phi^a, \phi^{\nu a}),$$  

(7.2)

and they can be explicitly written

$$\mathcal{L}_a(\phi) = \frac{\partial^2 \mathcal{L}}{\partial \phi^{\nu a}_{\mu \nu}} \phi^{\nu a}_{\mu \nu} + \frac{\partial^2 \mathcal{L}}{\partial \phi^{\nu a}_{\mu \nu} \partial \phi^b} \phi^{\nu a}_{\mu \nu} + \frac{\partial^2 \mathcal{L}}{\partial \phi^{\nu a}_{\mu \nu} \partial x^a} \frac{\partial \mathcal{L}}{\partial \phi^a} = 0$$  

(7.3)

by transparently exhibiting in this way their quasi-linear nature. When Eqs. (7.1) are linear, e.g., of the type

$$\mathcal{L}_a(\phi) = g^{\nu a} \phi^b_{\nu a} + \alpha^{\nu a}(x) \phi^b A^a + \beta_{\nu a}(x) \phi^b = 0,$$  

(7.4)

we shall write them in the customary form

$$\mathcal{L}_a(\phi) = \partial_{\nu} (\partial \mathcal{L} / \partial \phi^{\nu a}) - (\partial \mathcal{L} / \partial \phi^a) = 0.$$  

(7.5)

The reader should, however, be aware that form (7.5) is in general erroneous for our framework. We shall elaborate on this point later on in this section.

We shall say that Eqs. (7.1) are regular (degenerate) when their functional determinant (Hessian)

$$d_{LE} = d_{LE} (R_{LE}) = \left| \frac{\partial \mathcal{L}_a}{\partial \phi^{\nu a}_{\mu \nu}} \right| = \left| \frac{\partial \mathcal{L}_a}{\partial \phi^{\nu a}_{\mu \nu} \partial \phi^b} \right|$$  

(7.6)

is everywhere non-null (null) in a region $R_{LE}$ of its variables $(x_\nu, \phi^a, \phi^{\nu a})$ [35]. We shall also say that Eqs. (7.1) are of class $\mathcal{C}^m$ when the Lagrangian density $\mathcal{L}$ is of class $\mathcal{C}^{m+2}$, $m = 0, 1, 2, \ldots, \infty$ in $R_{LE}$ and vice versa.

We now restrict our analysis to Lagrange equations which are of at least class $\mathcal{C}^2$ and regular in $R_{LE}$, i.e.,

$$[\mathcal{L}_a(\phi)]^{\nu a,R} = 0.$$  

(7.7)

A central aspect of the problem of the identification of the representational capabilities of Eqs. (7.7) is the study of their variational properties. According to the methodology of Section 4, suppose that Eqs. (7.1) are computed along an $\alpha^3$-parameter family $\Phi(x; w) = \{\Phi(x; w), w \in O_\epsilon$ of solutions which is of at least class $\mathcal{C}^2$ in $R_{\Delta}(w)$. The equations of variation of Eqs. (7.7) along this family are given by

$$\Omega_{\alpha}(\eta) = (d \mathcal{L}_a / dw)|_{w=0} = \partial_{\mu} (\partial \mathcal{L} / \partial \eta^{\nu a}_\mu) - (\partial \mathcal{L} / \partial \eta^a) = 0,$$

$$a = 1, 2, \ldots, n, \quad \mu = 0, 1, 2, 3,$$  

(7.8)
where

\[
\Omega(x, \eta^n, \eta^{\nu n}) = \frac{1}{2} \left( \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_1}_{\mu_1} \eta^{\alpha_2}_{\nu_2} + 2 \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_1}_{\mu_1} \eta^{\alpha_2}_{\nu_2} + \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_1}_{\mu_1} \eta^{\alpha_2}_{\nu_2} \right)_{\nu = 0}.
\]  

Equations (7.8) are customarily called in the calculus of variations the \textit{Jacobi equations} and we shall preserve this terminology for our field theoretical framework too. More explicitly, Eqs. (7.8) can be written

\[
\Omega_a(\eta) = \left[ d_u \left( \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_1}_{\mu_1} + \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_2}_{\nu_2} \right) - \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_1}_{\mu_1} \eta^{\alpha_2}_{\nu_2} \right]_{\nu = 0}
\]

\[
+ \left[ d_u \left( \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_1}_{\mu_1} + \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_2}_{\nu_2} \right) - \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_1}_{\mu_1} \eta^{\alpha_2}_{\nu_2} \right]_{\nu = 0}
\]

\[
+ \left[ \frac{\partial^a \mathcal{L}}{\partial \phi^{\alpha_1}_{\mu_1} \partial \phi^{\alpha_2}_{\nu_2}} \eta^{\alpha_1}_{\mu_1} \eta^{\alpha_2}_{\nu_2} \right]_{\nu = 0}
\]

and they are the Euler equations of the "accessory minimum problem"

\[
A'(\eta) = \int_{R^a} d^3x \Omega(x, \eta^n, \eta^{\nu n}).
\]

Notice that the value of the functional determinant of Eqs. (7.1), when computed along a family of solutions, coincides with the functional determinant of Eqs. (7.8). Therefore, when the Lagrange equations are regular, so are the Jacobi equations (and vice versa). More generally, the properties

\[
[\Omega_a(\eta)]^\xi = 0
\]

are a direct consequence of assumptions (7.7).

Equations (7.8) are strikingly similar in structure to the Lagrange equations. Nevertheless, Eqs. (7.7) and (7.8) are not equivalent, namely, they admit different families of solutions, unless Eqs. (7.7) are linear homogeneous, i.e., of type (7.4). Indeed, the Jacobi equations of system (7.4) are

\[
\Omega_a(\eta) = g^{\alpha_1}_{\mu_1} \eta^{\alpha_1}_{\mu_1} + \alpha^{\alpha_1}_{\mu_1}(x) \eta^{\alpha_1}_{\mu_1} + \beta^{\alpha_1}_{\mu_1}(x) \eta^{\alpha_1}_{\mu_1} = 0,
\]

and, trivially, the families of solutions of Eqs. (7.4) and (7.13) coincide. In essence,
the Lagrange equations are generally quasi-linear while the Jacobi equations are always linear and, thus, these two systems are not necessarily equivalent.

The adjoint system of variations of the Lagrange equations, from definition (5.6), is given by

\[
\Omega_a(\eta) = \tilde{\eta}^\mu \left[ d_a \left( \frac{\partial^2 \mathcal{L}}{\partial \phi^a \partial \phi} \right) - \frac{\partial \mathcal{L}}{\partial \phi^a} \right]_{\eta=0} - d_e \left\{ \eta^\nu \left[ d_e \left( \frac{\partial^2 \mathcal{L}}{\partial \phi^e \partial \phi^a} \right) + \frac{\partial \mathcal{L}}{\partial \phi^e} \frac{\partial \phi^a}{\partial \phi^e} \right]_{\eta=0} \right\} + d_a d_e \left( \eta^\nu \frac{\partial \mathcal{L}}{\partial \phi^a \partial \phi^e} \right)_{\eta=0} \\
= \tilde{\eta}^\mu \left[ d_a \left( \frac{\partial^2 \mathcal{L}}{\partial \phi^a \partial \phi^e} \right) - \frac{\partial \mathcal{L}}{\partial \phi^a} \right]_{\eta=0} + \eta^\nu \left[ d_e \left( \frac{\partial^2 \mathcal{L}}{\partial \phi^e \partial \phi^a} \right) + \frac{\partial \mathcal{L}}{\partial \phi^e} \frac{\partial \phi^a}{\partial \phi^e} \right]_{\eta=0} + \eta^\nu \frac{\partial \mathcal{L}}{\partial \phi^a} \left( \frac{\partial \mathcal{L}}{\partial \phi^e} \right)_{\eta=0} \right. \\
\left. + \eta^\nu \frac{\partial \mathcal{L}}{\partial \phi^a} \frac{\partial \mathcal{L}}{\partial \phi^e} \right]_{\eta=0}. 
\tag{7.14}
\]

The following theorem can now be trivially proved.

**Theorem 7.1.** Class \(C^2\) regular Lagrange equations for tensorial fields are always self-adjoint in their region of definition.

Notice that the identity of the Jacobi equations (7.8) with the adjoint system (7.14), i.e.,

\[
\Omega_a(\eta) \equiv \tilde{\Omega}_a(\eta), 
\tag{7.15}
\]

reduces to the identities

\[
d_e \left( \frac{\partial \mathcal{L}}{\partial \phi^e \partial \phi^a} \right) \equiv d_a \left( \frac{\partial \mathcal{L}}{\partial \phi^a \partial \phi^e} \right) \\
\left( \frac{\partial \mathcal{L}}{\partial \phi^e} \right) \frac{\partial \phi^a}{\partial \phi^e} \equiv \left( \frac{\partial \mathcal{L}}{\partial \phi^a} \right) \frac{\partial \phi^e}{\partial \phi^a} \\
\left( \frac{\partial \mathcal{L}}{\partial \phi^a} \right) \frac{\partial \phi^e}{\partial \phi^a} \equiv \left( \frac{\partial \mathcal{L}}{\partial \phi^e} \right) \frac{\partial \phi^a}{\partial \phi^e} \\
\left( \frac{\partial \mathcal{L}}{\partial \phi^a} \right) \frac{\partial \phi^e}{\partial \phi^a} \frac{\partial \phi^f}{\partial \phi^e} \equiv \left( \frac{\partial \mathcal{L}}{\partial \phi^a} \right) \frac{\partial \phi^f}{\partial \phi^a},
\tag{7.16}
\]

which are always satisfied in view of the assumed continuity properties of the Lagrangian density.

Theorem 7.1 can be proved in several other ways. For instance, although it is more laborious, one can prove the equations' self-adjointness by showing that all conditions (6.10) or (6.14) are verified for Eqs. (7.7). This is left as an exercise for the interested reader. For comments on this point see the end of this section.
Notice that the assumption $L \in \mathcal{C}(R_{\bar{E}})$ is sufficient to establish the continuity of the Jacobi equations but it is generally insufficient for the continuity of the adjoint system in view of the fourth-order derivatives appearing in Eqs. (7.14).

We must now inspect the structure of the conserved current density associated with the Lagrange identity (5.1). From definition (5.7) and Eqs. (7.10) we can write

$$J^a(\eta, \bar{\eta}) = \bar{\eta}^a \eta^b \bar{\eta}_b + \bar{\eta}^a \epsilon^b_{\mu \nu} \eta^{\mu \nu} - \left[ \partial_v \left( \phi_{\bar{a}} \phi_{\bar{b}} \right) \right] \eta^b$$

$$= \bar{\eta}^a \left[ d_v \left( \frac{\partial^2 L}{\partial \phi^{\bar{a}_u} \partial \phi^{\bar{b}_u}} \right) - \frac{\partial^2 L}{\partial \phi^{\bar{a}_u} \partial \phi^{\bar{b}_u}} \right] \eta^b$$

$$+ \frac{\partial^2 L}{\partial \phi^{\bar{a}_v} \partial \phi^{\bar{b}_v}} \eta^{\mu \nu} - \left\{ d_v \left[ \bar{\eta}^a \frac{\partial^2 L}{\partial \phi^{\bar{a}_v} \partial \phi^{\bar{b}_v}} \right] \right\} \bar{\eta}^a \eta^b$$

$$= \bar{\eta}^a \left( \frac{\partial^2 L}{\partial \phi^{\bar{a}_u} \partial \phi^{\bar{b}_u}} \right) - \frac{\partial^2 L}{\partial \phi^{\bar{a}_u} \partial \phi^{\bar{b}_u}} \right] \eta^b$$

$$+ \frac{\partial^2 L}{\partial \phi^{\bar{a}_v} \partial \phi^{\bar{b}_v}} \eta^{\mu \nu} - \bar{\eta}^a \left( \frac{\partial^2 L}{\partial \phi^{\bar{a}_v} \partial \phi^{\bar{b}_v}} \right) \eta^b$$

$$+ \bar{\eta}^a \left( d_v \left( \frac{\partial^2 L}{\partial \phi^{\bar{a}_v} \partial \phi^{\bar{b}_v}} \right) - d_v \left( \frac{\partial^2 L}{\partial \phi^{\bar{a}_v} \partial \phi^{\bar{b}_v}} \right) \right) \bar{\eta}^a \eta^b. \quad (7.17)$$

The reader should be alerted that a proper symmetrization of the indices of the above expressions is here tacitly assumed. We shall comment on this point later on in this section.

When the terms within brackets are computed along a solution of the Lagrange equations and the current $J^a$ is restricted along the solutions of the Jacobi equations, we have $\eta \equiv \bar{\eta}$ and $J^a \equiv 0$, $\mu = 0, 1, 2, 3$.

It should be noted that Theorem 7.1 is a variational formulation of the known property that the Lagrange operator

$$L_a = d_m \left( \partial / \partial \phi^{\bar{a}_m} \right) \eta \left( \partial / \partial \phi^{\bar{a}} \right)$$

is self-adjoint in the conventional sense of the theory of linear operator [36]. This also indicates the reason for preserving the term "self-adjointness" in our variational treatment. We would also like to indicate that, according to our best knowledge at this time, the variational approach to self-adjointness appears to be more effective than the operational approach for the problem of identifying the conditions under which a Lagrangian exists in classical field theories, as we shall see better in the subsequent papers. It is for this reason that we have preferred the former over the latter approach.

A few comments on the structure of the Lagrange equations are in order. First of all let us note that, as the reader can verify with a simple inspection, in the currently available textbooks in field theory the Lagrange equations are written
with partial derivatives \( \partial_a \), as in form (7.5), while in all textbooks in the calculus of variations for multiple integrals such equations are written with total derivatives \( d_a \), as in form (7.1) or (7.3). In the opinion of this author, the former approach is incorrect while the latter is correct. This is due to the fact that the proper handling of the variational techniques which underlie the derivation of such equations from an action principle demands the use of the total rather than partial derivatives. Besides, if Eqs. (7.5) were correct, then their Newtonian counterpart should be given by the form

\[
\frac{\partial}{\partial t} \frac{\partial L(t, q, \dot{q})}{\partial \dot{q}_k} - \frac{\partial L(t, q, \dot{q})}{\partial q_k} = 0, \quad k = 1, 2, \ldots, n, \tag{7.19}
\]

which is known to be erroneous, while the correct form is that of Eqs. (1.4).

The above remark, however, must be put in its proper perspective. Indeed, for the vast majority of Lagrangian densities used nowadays, which are essentially constituted by a kinetic term plus an additive term, as in the form

\[
\mathcal{L} = \frac{1}{2} \phi^{\mu \nu} \phi_{\mu \nu} + B(\phi), \tag{7.20}
\]

Eqs. (7.3) and (7.5) produce identical equations of motion, in which case they are equivalent for all practical purposes. This, however, is no longer the case for more general models, such as chiral Lagrangians of the type

\[
\mathcal{L} = \frac{1}{2} \phi_{\mu \nu} C^{\beta \gamma}(\phi) \phi_{\beta \gamma} + B(\phi). \tag{7.21}
\]

The analysis of these papers relates to Lagrangian densities which, besides satisfying the assumed continuity, regularity, and Lorentz-invariance conditions, have an arbitrary functional dependence in their arguments. As a result, the proper form of the Lagrange equations is (7.1) or (7.3).

It should be indicated that these Lagrangians, in general, satisfy the properties

\[
(\partial^n \mathcal{L}/\partial \phi^{\mu_1} \cdots \partial \phi^{\mu_n}) \neq (\partial^n \mathcal{L}/\partial \phi^{\mu_1} \cdots \partial \phi^{\mu_n})
\]  

(7.22)

without being in conflict with the continuity assumptions, i.e.,

\[
(\partial^n \mathcal{L}/\partial \phi^{\mu_1} \cdots \partial \phi^{\mu_n}) = (\partial^n \mathcal{L}/\partial \phi^{\mu_1} \cdots \partial \phi^{\mu_n})
\]  

(7.23)

This fact demands few comments in relation to our variational approach to self-adjointness. Indeed, properties (7.22) are in apparent violation of the conditions of self-adjointness (6.10a) or (6.14a). This apparent contradiction is, however, easily resolved by recalling, from Section 3, that the terms \( \partial^n \mathcal{L}/\partial \phi^{\mu_1} \cdots \partial \phi^{\mu_n} \) are
contrasted with the totally symmetric derivatives \( \phi^{i}_{\nu \sigma} = \phi^{i}_{\sigma \nu} \). As a result, Eqs. (7.3) can be equivalently written

\[
\mathcal{L}_{\phi}(\phi) = \frac{1}{2} \left( \frac{\partial^{2} \mathcal{L}}{\partial \phi^{i}_{\mu \nu} \partial \phi^{i}_{\nu \mu}} + \frac{\partial^{2} \mathcal{L}}{\partial \phi^{i}_{\mu \nu} \partial \phi^{i}_{\nu \mu}} \right) \phi^{i}_{\mu \nu} + \frac{\partial \mathcal{L}}{\partial \phi^{i}_{\mu \nu}} \phi^{i}_{\mu \nu}
+ \frac{\partial \mathcal{L}}{\partial \phi^{i}_{\mu \nu}} \frac{\partial \mathcal{L}}{\partial \phi^{i}_{\sigma \nu}} \phi^{i}_{\sigma \nu}
= 0
\]  

(7.24)

in view of the identities

\[
\frac{1}{2} \left( \frac{\partial \mathcal{L}}{\partial \phi^{i}_{\mu \nu}} - \frac{\partial \mathcal{L}}{\partial \phi^{i}_{\nu \mu}} \right) \phi^{i}_{\mu \nu} = 0.
\]  

(7.25)

Of course the same symmetrization applies for the the Jacobi equations (7.10). The conditions of self-adjointness (6.10a), i.e.,

\[
\frac{\partial \mathcal{L}_{a}}{\partial \phi^{i}_{\mu \nu}} = \frac{\partial \mathcal{L}_{a}}{\partial \phi^{i}_{\nu \mu}},
\]  

are therefore identically verified for Eqs. (7.24) in view of the assumed continuity conditions of the Lagrangian density.

Throughout these papers we shall tacitly assume that, whenever properties (7.22) hold, the explicit form of the Lagrange equations is given by Eqs. (7.24).

It might be of some significance to indicate the criterion we have followed in deriving and presenting the conditions of self-adjointness (6.10). In essence, such conditions were derived (by having in mind the structure of the Lagrange equations) first for the general case (7.22), and then the symmetry of those terms in the greek indices was imposed. As a result, the first identities in the lhs of Eqs. (6.10), i.e.,

\[
\frac{\partial \mathcal{F}_{a}}{\partial \phi^{i}_{\mu \nu}} = \frac{\partial \mathcal{F}_{b}}{\partial \phi^{i}_{\nu \mu}},
\]  

(7.27a)

\[
\frac{\partial \mathcal{F}_{a}}{\partial \phi^{i}_{\mu \nu}} + \frac{\partial \mathcal{F}_{b}}{\partial \phi^{i}_{\nu \mu}} = d_{\nu} \left( \frac{\partial \mathcal{F}_{a}}{\partial \phi^{i}_{\nu \mu}} + \frac{\partial \mathcal{F}_{b}}{\partial \phi^{i}_{\nu \mu}} \right),
\]  

(7.27b)

\[
\frac{\partial \mathcal{F}_{a}}{\partial \phi^{i}_{\mu \nu}} - \frac{\partial \mathcal{F}_{b}}{\partial \phi^{i}_{\nu \mu}} = \frac{1}{2} d_{\nu} \left( \frac{\partial \mathcal{F}_{a}}{\partial \phi^{i}_{\nu \mu}} - \frac{\partial \mathcal{F}_{b}}{\partial \phi^{i}_{\nu \mu}} \right),
\]  

(7.27c)

apply for the Lagrange equations in the form (7.3). The full set of conditions of self-adjointness (6.10) must, however, be applied to the Lagrange equations in their actual form (7.24).

This produces an alternative to our proof of Theorem 7.1, namely, that class \( A^{2} \), regular Lagrange equations are self-adjoint.
A further alternative proof of this crucial property can be achieved by using the conditions of self-adjointness of the quasi-linear form, i.e., Eqs. (6.14). In this case, however, the use of the actual form (7.24) of the Lagrange equations is advisable.

8. ANALYTIC REPRESENTATIONS

The main objective of these papers is to assign a given (covariant, tensorial) system of quasi-linear field equations and then study the conditions under which a Lagrangian density capable of "representing" that system exists. For this objective it is essential to clarify the concept of an "analytic representation," namely, a representation of the system in terms of the Lagrange equations.

In principle, we can say that given a quasi-linear system of field equations

\[ [A_{\alpha\beta}(\phi^a, \phi^b, \phi^{a\beta})]_{\mu\nu} + B_{\alpha}(\phi^a, \phi^b, \phi^{a\beta})] = 0, \quad (8.1) \]

its "analytic representation" in terms of the Lagrange equations

\[ [\mathcal{L}_a(\phi)]^{\phi^a}_{\mu\nu} = 0 \quad (8.2) \]

exists when the general solutions [37] of systems (8.1) and (8.2) coincide. In practice, however, the above definition can predictably be faced with severe difficulties, e.g., when the equations are nonlinear or when they admit singular solutions.

In order to circumvent these difficulties we shall say that Eqs. (8.1) admit an analytic representation in terms of Eqs. (8.2) in a region \( R_{ab} \) of points \( (x, \phi^a, \phi^b) \) where there exist \( n \) functions \( h_{ab} = h_{ab}(x, \phi^a, \phi^b) \) which are of at least class \( \mathcal{C}^2 \) and whose matrix \( (h_{ab}) \) is everywhere regular in \( R_{ab} \), such that

\[ [\mathcal{L}_a(\phi)]^{\phi^a}_{\mu\nu} = [h_{ab}(A_{\alpha\beta}^{\phi^a_{\mu\nu}} + B_{\alpha})]^{\phi^a}_{\mu\nu} = 0, \quad a = 1, 2, \ldots, n. \quad (8.3) \]

Alternatively, we can say that an analytic representation exists when the Lagrange equations coincide with the field equations up to an equivalence transform, i.e.,

\[ [g_1^{\alpha\beta}[\mathcal{L}_a(\phi)]^{\phi^a}_{\mu\nu}]_{\mu\nu} = [A_{\alpha\beta}^{\phi^a_{\mu\nu}} + B_{\alpha}]^{\phi^a}_{\mu\nu} = 0, \quad a = 1, 2, \ldots, n. \quad (8.4) \]

Clearly, definitions (8.3) and (8.4) are equivalent. Since both matrices \( (h_{ab}) \) and \( (g_1^{\alpha\beta}) \) are everywhere regular in \( R_{ab} \) by assumption, their inverses, say \( (h^{-1}_{ab}) \) and \( (g^{-1}_1)^{\alpha\beta} \), exist. When representation (8.3) exists for given \( \mathcal{L} \) and \( h_{ab} \), then representation (8.4) exists too, trivially, with \( g_1^{\alpha\beta} = h^{-1}_{ab} \) and vice versa. Notice that we exclude a dependence of the factor functions \( h_{ab} \) or \( g_1^{\alpha\beta} \) on the second-order derivatives, although we do assume a possible nontrivial dependence in \( (x, \phi^a, \phi^{a\beta}) \).
A LAGRANGIAN IN FIELD THEORY. 1

The first significant implication of definitions (8.3) and (8.4) is that, given a (quasilinear, covariant, tensorial) system of field equations, the knowledge of only one function, the Lagrangian density, is generally insufficient to characterize an analytic representation because \((n^2 + 1)\)-functions are generally needed, i.e., the Lagrangian density \(L\) and \(n^2\) factor functions \(h_a^b\) or \(g_a^b\). This fact, which will have an impact at several levels of our analysis, will be better elaborated later on.

The second implication of definitions (8.3) and (8.4) is that they indicate the existence of the following generalized form of the Lagrange equations,

\[
g_a^b(x_a, \phi^a, \phi^{a_i}) \left[ d_{ab} \frac{\partial L(x_a, \phi^a, \phi^{a_i})}{\partial \phi^{a_i}} - \frac{\partial L(x_a, \phi^a, \phi^{a_i})}{\partial \phi^{a_i}} \right] = 0, \quad (8.5)
\]

which originates from the lhs of Eqs. (8.4).

Equations (8.5) are significant for the following reasons:

1. They can be formulated in a way consistent with the customary Lorentz covariance for a suitable selection of the \((n^2 + 1)\)-functions \((g_a^b, L)\).
2. They contain the conventional equations, trivially, at the limit \((g_a^b, L) \rightarrow (\delta_a^b, L)\).
3. They are in general non-self-adjoint, as the reader can verify by inspection. This removes the somewhat restrictive character of the conventional Lagrange equations of being always self-adjoint (Theorem 7.1) with a significant broadening of the methodology for the representation of the field equations.
4. They transparently exhibit the need of \((n^2 + 1)\)-functions for the characterization of an analytic representation which is somewhat hidden in the conventional approach.
5. They are significant for the transformation theory of the Lagrangian, (as we shall see better in the next section) because, under the assumption of regularity of the matrix \((g_a^b)\) of the factor terms, they are simple equivalence transformations of the conventional equations.

We plan to study Eqs. (8.5) in more detail in a subsequent paper, with the intent of exploring their derivation from variational principles. If this property can be successfully established, then Eqs. (8.5) are bona fide analytic equations (as are the conventional ones).

Another implication of definitions (8.3) and (8.4) is that they are sufficiently general to justify the identification of some significant subcases. In turn, as we shall see in a subsequent paper, the question whether the conditions of self-adjointness are only sufficient or both necessary and sufficient, centrally depends on the assumed type of analytic representation.
As a first subdivision of definition (8.3) we shall say that an analytic representation is \textit{direct (indirect)} when the matrix \((h^a_b)\) of the factor functions reduces (does not reduce) to the unit matrix, i.e., when \(h^a_b = \delta^a_b(h^a_c \neq \delta^a_c)\).

The above distinction between “direct” and “indirect” representations will play a significant role, particularly when complex fields are involved.

Consider, for simplicity, the case of linear field equations. Then, representation (8.3), under the restriction of being direct, reads

\[
\frac{\partial^2 \mathcal{L}}{\partial \phi_i^{\alpha u}} \frac{\partial \phi^i_{\alpha u}}{\partial x^v} + \frac{\partial^2 \mathcal{L}}{\partial \phi_i^{\beta u}} \frac{\partial \phi^i_{\beta u}}{\partial x^v} - \frac{\partial \mathcal{L}}{\partial \phi^a} = 0. \tag{8.6}
\]

Therefore, the Lagrange equations in the component \(\phi_a, a = \text{fixed},\) must be identical with the field equation in the same component \(\phi_a\). It is easy to see that this framework is insufficient for the analytic representation of complex fields according to the Lagrangian densities customarily used nowadays. Indeed, for these Lagrangians the Lagrange equations in one component, say \(\phi_a\), usually generate the field equation in the complex conjugate component, say \(\bar{\phi}_a\), in which case direct identification (8.6) does not hold.

A simple example may help to illustrate this concept. Consider, for simplicity, the Lagrangian of a free complex scalar field

\[
\mathcal{L} = \bar{\phi}^i \phi_i - m^2 \phi \bar{\phi}. \tag{8.7}
\]

Then the Lagrange equations generate an “indirect” rather than a “direct” representation because

\[
\begin{pmatrix}
\partial_k 
\frac{\partial \mathcal{L}}{\partial \phi_k} - \frac{\partial \mathcal{L}}{\partial \phi}
\partial_k 
\frac{\partial \mathcal{L}}{\partial \bar{\phi}_k} - \frac{\partial \mathcal{L}}{\partial \bar{\phi}}
\end{pmatrix} = \begin{pmatrix}
0 & 1
1 & 0
\end{pmatrix} \begin{pmatrix}
\square + m^2 \phi
\square + m^2 \phi
\end{pmatrix} = 0. \tag{8.8}
\]

Clearly, this is a subcase of the more general definition (8.3) which occurs when the factor terms \(h_a^b\) simply represent a permutation of the indices. This remark should not be construed to imply that a “direct” representation for the complex scalar field does not exist. Indeed, a simple inspection indicates that the \textit{different} Lagrangian

\[
\mathcal{L} = \frac{1}{2}(\phi^i \phi_i - m^2 \phi^2) + \text{c.c.} \tag{8.9}
\]
does indeed produce the "direct" representation

\[
\begin{pmatrix}
\partial_{\mu} \frac{\partial \mathcal{L}^*}{\partial \phi_{\mu}^{*}} - \frac{\partial \mathcal{L}^*}{\partial \phi_{\mu}} \\
\partial_{\nu} \frac{\partial \mathcal{L}^*}{\partial \phi_{\nu}^{*}} - \frac{\partial \mathcal{L}^*}{\partial \phi_{\nu}}
\end{pmatrix}
= \begin{pmatrix}
(\Box + m^2) \phi \\
(\Box + m^2) \bar{\phi}
\end{pmatrix} = 0.
\tag{8.10}
\]

Notice that both Lagrangians \( \mathcal{L} \) and \( \mathcal{L}^* \) are Hermitian, and that on strict grounds the Lagrangian \( \mathcal{L}^* \) alone is sufficient to characterize an analytic representation (8.10) while \( \mathcal{L} \) is not. Indeed, representation (8.8) demands a Lagrangian and four elements of the factor functions \( h_{a}^{*} \).

It should be indicated that in ultimate analysis the question of whether a representation is direct or indirect is immaterial because it merely relates to the assumed form of the field equations. For instance, the equations in the complex scalar field can be assigned in the reverse ordering. Then representation (8.8) becomes direct and Eqs. (8.10) become indirect. What is significant for the transformation theory is the possible existence of both direct and indirect representations for a given system. This point will be further elaborated in the next section.

The above differentiation of analytic representations into direct and indirect categories is insufficient for our analysis because it does not provide information on the behavior of the equations of variation.

As we have learned from the analysis of Section 6, all free tensorial field equations in their conventional form are self-adjoint. However, when interacting fields are considered, the systems can be either self-adjoint or non-self-adjoint. As we shall see, an analytic representation may exist in each of these cases.

This indicates the need to complete definitions (8.3) and (8.4) in such a way as to ensure the self-adjointness of the rhs as dictated by Theorem 7.1 on the self-adjointness of the Lagrange equations.

We shall say that Eqs. (8.1) admit an ordered (nonordered) analytic representation in a region \( R_{1,2} \) of points \( (x, \phi, \phi^{*}) \) when the lhs and the rhs of identifications (8.3) or (8.4) coincide in a given ordering (without an ordering) of all the values \( a = 1, 2, ..., n \). More explicitly, the concept of ordered analytic representation demands that the systems of equations in the lhs and rhs of identifications (8.3) and (8.4) are not only identical, but they coincide member by member for a given ordering of the index \( a \) and we shall symbolically write

\[
\mathcal{L}_{a}(\phi) \equiv F_{a}(\phi), \quad a = 1, 2, ..., n.
\tag{8.11}
\]

On the contrary, the concept of nonordered analytic representations demands that the systems of equations in the lhs and the rhs of identifications (8.3) and (8.4) only coincide without any reference as far as the ordering of such systems is concerned, and we shall symbolically write

\[
\{\mathcal{L}_{a}(\phi)\} \equiv \{F_{a}(\phi)\}, \quad a, b = 1, 2, ..., n.
\tag{8.12}
\]
Since the r.h.s. of cases (8.11) and (8.12) coincide as systems by assumption, the only possible difference which is admissible is a permutation of the indices.

We now particularize the ordered and nonordered analytic representations as either direct or indirect, depending respectively, on whether the factor functions $h_a^b$ are trivial ($h_a^b = \delta_a^b$) or not ($h_a^b \neq \delta_a^b$).

As we shall see, the concept of ordering has a rather significant impact in the methodology which underlies all analytic representations.

Let us first remark in this respect that the term "ordered direct analytic representation" implies that each of the following three sets of identities (for class $\mathcal{Q}^2$ and regular systems)

\begin{align*}
\mathcal{L}_a(\phi) &= F_a(\phi), \\
\mathcal{L}_a(\eta) &= M_a(\eta), \\
\mathcal{L}_a(\eta) &= \tilde{M}_a(\eta),
\end{align*}

holds in the assumed order. This is a consequence of Theorem 7.1. Indeed, since the l.h.s of the analytic representation (i.e., the Lagrange equations) is self-adjoint, the r.h.s must be self-adjoint, too. But the equations of variations and the adjoint systems are (under the assumed conditions) unique, so all the identifications (8.13) hold.

Explicitly, such representation implies that all the following conditions hold: (a) The system of Lagrange equations in a given ordering coincides with the field equations in the same ordering; (b) the Jacobi equations in the above ordering coincide with the equations of variations of the field equations in the same ordering; (c) the adjoint system of the Jacobi equations coincides with the adjoint system of the field equations in the same ordering.

A simple example of ordered direct analytic representations is given by Eqs. (8.10), which we now rewrite

\begin{equation}
\left[\mathcal{L}_a \phi_s\right]_{\text{SA}} = \left[\Box + m^2\right] \phi_s \Big|_{\text{SA}}.
\end{equation}

Similarly, the term "ordered indirect analytic representation" implies that each of the three sets of identities (again for class $\mathcal{Q}^2$ and regular systems)

\begin{align*}
\mathcal{L}_a(\phi) &= h_a^b F_b(\phi), \\
\mathcal{L}_a(\eta) &= M_a^{Ra}(\eta), \\
\mathcal{L}_a(\eta) &= \tilde{M}_a^{Ra}(\eta),
\end{align*}

holds in the assumed order. This is a consequence of Theorem 7.1. Indeed, since the l.h.s of the analytic representation (i.e., the Lagrange equations) is self-adjoint, the r.h.s must be self-adjoint, too. But the equations of variations and the adjoint systems are (under the assumed conditions) unique, so all the identifications (8.13) hold.

Explicitly, such representation implies that all the following conditions hold: (a) The system of Lagrange equations in a given ordering coincides with the field equations in the same ordering; (b) the Jacobi equations in the above ordering coincide with the equations of variations of the field equations in the same ordering; (c) the adjoint system of the Jacobi equations coincides with the adjoint system of the field equations in the same ordering.

A simple example of ordered direct analytic representations is given by Eqs. (8.10), which we now rewrite

\begin{equation}
\left[\mathcal{L}_a \phi_s\right]_{\text{SA}} = \left[\Box + m^2\right] \phi_s \Big|_{\text{SA}}.
\end{equation}

Similarly, the term "ordered indirect analytic representation" implies that each of the three sets of identities (again for class $\mathcal{Q}^2$ and regular systems)

\begin{align*}
\mathcal{L}_a(\phi) &= h_a^b F_b(\phi), \\
\mathcal{L}_a(\eta) &= M_a^{Ra}(\eta), \\
\mathcal{L}_a(\eta) &= \tilde{M}_a^{Ra}(\eta),
\end{align*}

holds in the assumed order. This is a consequence of Theorem 7.1. Indeed, since the l.h.s of the analytic representation (i.e., the Lagrange equations) is self-adjoint, the r.h.s must be self-adjoint, too. But the equations of variations and the adjoint systems are (under the assumed conditions) unique, so all the identifications (8.13) hold.

Explicitly, such representation implies that all the following conditions hold: (a) The system of Lagrange equations in a given ordering coincides with the field equations in the same ordering; (b) the Jacobi equations in the above ordering coincide with the equations of variations of the field equations in the same ordering; (c) the adjoint system of the Jacobi equations coincides with the adjoint system of the field equations in the same ordering.

A simple example of ordered direct analytic representations is given by Eqs. (8.10), which we now rewrite

\begin{equation}
\left[\mathcal{L}_a \phi_s\right]_{\text{SA}} = \left[\Box + m^2\right] \phi_s \Big|_{\text{SA}}.
\end{equation}

Similarly, the term "ordered indirect analytic representation" implies that each of the three sets of identities (again for class $\mathcal{Q}^2$ and regular systems)

\begin{align*}
\mathcal{L}_a(\phi) &= h_a^b F_b(\phi), \\
\mathcal{L}_a(\eta) &= M_a^{Ra}(\eta), \\
\mathcal{L}_a(\eta) &= \tilde{M}_a^{Ra}(\eta),
\end{align*}

holds in the assumed order. This is a consequence of Theorem 7.1. Indeed, since the l.h.s of the analytic representation (i.e., the Lagrange equations) is self-adjoint, the r.h.s must be self-adjoint, too. But the equations of variations and the adjoint systems are (under the assumed conditions) unique, so all the identifications (8.13) hold.

Explicitly, such representation implies that all the following conditions hold: (a) The system of Lagrange equations in a given ordering coincides with the field equations in the same ordering; (b) the Jacobi equations in the above ordering coincide with the equations of variations of the field equations in the same ordering; (c) the adjoint system of the Jacobi equations coincides with the adjoint system of the field equations in the same ordering.

A simple example of ordered direct analytic representations is given by Eqs. (8.10), which we now rewrite

\begin{equation}
\left[\mathcal{L}_a \phi_s\right]_{\text{SA}} = \left[\Box + m^2\right] \phi_s \Big|_{\text{SA}}.
\end{equation}

Similarly, the term "ordered indirect analytic representation" implies that each of the three sets of identities (again for class $\mathcal{Q}^2$ and regular systems)

\begin{align*}
\mathcal{L}_a(\phi) &= h_a^b F_b(\phi), \\
\mathcal{L}_a(\eta) &= M_a^{Ra}(\eta), \\
\mathcal{L}_a(\eta) &= \tilde{M}_a^{Ra}(\eta),
\end{align*}

holds in the assumed order. This is a consequence of Theorem 7.1. Indeed, since the l.h.s of the analytic representation (i.e., the Lagrange equations) is self-adjoint, the r.h.s must be self-adjoint, too. But the equations of variations and the adjoint systems are (under the assumed conditions) unique, so all the identifications (8.13) hold.

Explicitly, such representation implies that all the following conditions hold: (a) The system of Lagrange equations in a given ordering coincides with the field equations in the same ordering; (b) the Jacobi equations in the above ordering coincide with the equations of variations of the field equations in the same ordering; (c) the adjoint system of the Jacobi equations coincides with the adjoint system of the field equations in the same ordering.

A simple example of ordered direct analytic representations is given by Eqs. (8.10), which we now rewrite

\begin{equation}
\left[\mathcal{L}_a \phi_s\right]_{\text{SA}} = \left[\Box + m^2\right] \phi_s \Big|_{\text{SA}}.
\end{equation}
holds in a given ordering where the differential forms $M^{\text{eq}}_a$ and $\tilde{M}^{\text{eq}}_a$ are now computed for the equivalent systems rather than the original systems.

A simple example of an ordered indirect analytic representation is given by Eqs. (8.8), which we now rewrite

$$
\begin{bmatrix}
0 & 1 \\
1 & 0 \\
\end{bmatrix}
\begin{bmatrix}
\begin{pmatrix} m^2 \end{pmatrix} & \varphi \\
\end{pmatrix}
\begin{pmatrix} \bar{\varphi} \\
\end{pmatrix}
\right). 
$$

\text{(8.16)}

This author was surprised that the above properties do not necessarily hold for nonordered analytic representations. More specifically, if the ordering is ignored, then the following case, for instance, is possible:

$$
\begin{align*}
\{ L_a(\phi) \} &= \{ h_s F_c(\phi) \}, \\
\{ \Omega_a(\eta) \} &= \{ M^{\text{eq}}_a(\eta) \}, \\
\{ \tilde{\Omega}_a(\eta) \} &\neq \{ \tilde{M}^{\text{eq}}_a(\eta) \} .
\end{align*}
\text{(8.17)}
$$

The external bracket indicates that the included quantities are considered as systems rather than term by term.

It is essential to verify with an example that representations of type (8.17) do exist. And indeed, the case of the complex scalar field in interaction with the electromagnetic field provides one of the most significant examples for both ordered and nonordered analytic representations.

Consider the familiar gauge invariant Lagrangian density

$$
L = -\frac{1}{2} A_{\mu}^{\ast} A^{\ast}, + \bar{\varphi} \varphi + m^2 \bar{\varphi} \varphi \\
+ \bar{\varphi} A_{\mu} A^{\ast} \varphi - i e (\bar{\varphi} A_{\mu} \varphi - \bar{\varphi} A^{\ast} \varphi) A^{\ast}. 
$$

\text{(8.18)}

Explicit calculations, which are given for the reader's convenience in Appendix C, prove that the ordered analytic representation produced by this Lagrangian is of the type

$$
\begin{bmatrix}
0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 1 & 0 \\
\end{bmatrix}
\begin{bmatrix}
\begin{pmatrix} m^2 \end{pmatrix} & \varphi \\
\end{pmatrix}
\begin{pmatrix} \bar{\varphi} \\
\end{pmatrix}
\right). 
$$

\text{(8.19)}

namely, as shown in Section 6 (also see Table I), the field equations are non-self-adjoint; nevertheless, when the ordering in which they are written is taken into account, they admit a form which coincides member by member with the analytic equations in the Lagrangian (8.18); as a consequence, they became self-adjoint.
Now if the ordering is ignored, the Lagrangian (8.18) characterizes the non-ordered analytic representation

\[
\{\mathcal{L}_a(\phi)\}_\text{SA} = \left\{\begin{array}{c}
-\Box A_u + ie(\bar{\psi}_u + ieA_u \bar{\phi}) C - \bar{\phi}(\bar{\psi}_u - ieA_u \phi) \\
\Box + m^2 - e^2 A_u A^u \end{array}\right\} \phi - 2ieA^u \bar{\phi}_u,
\]

\[
\Box + m^2 - e^2 A_u A^u \phi + 2ieA^u \bar{\phi}_u \right\}_\text{NSA},
\]

which has precisely the structure (8.17) (see Appendix C for more details).

The impact of the concept of ordering in the methodology of the analytic representations is now self-evident. Indeed, if this concept is ignored, one might arrive at the erroneous conclusion that the familiar field equations for the complex scalar field in interaction with the electromagnetic field, since they are non-self-adjoint in the form (6.37), do not admit an analytic representation contrary to a rather old and well-established knowledge in field theory.

The significance of the concept of ordering for our program can now be easily anticipated. Indeed, since we are interested in the necessary and sufficient conditions for the existence of a Lagrangian in field theory, the existence of structures of type (8.17) clearly affects the necessity of such conditions. This point will be elaborated in paper II.

As a refinement of the above remarks, let us note that the term "ordered indirect analytic representation" leaves full freedom on the ordering of the internal sum with respect to the \(b\) index of the identification (8.3). In other words, the ordering requirement refers only to the external index \(a\) for the identification of the equivalent system of field equations with the Lagrange equations member by member. However, the sum with respect to the \(b\) index relative to the factor terms \(h^a_b\) is unrestricted as far as the ordering is concerned. This remark is also significant; indeed, it implies the existence of the following classification of the ordered indirect analytic representations

\[
are written is ignored, then there exist the two Lagrangians (8.7) and (8.9) which produce the same system. Again this property has its own significance for the transformation theory.

9. The Problem of Equivalent Analytic Representations

It is well known that a Lagrangian density capable of representing quasi-linear systems of field equations is not unique. The physical significance of the underlying "degree of freedom" has become even more transparent in recent times, particularly in the framework of the unified gauge theories [38]. In the opinion and to the best knowledge of this author such "degrees of freedom" of the Lagrangian density have been only partially identified until now.

In this section we shall point out the possible existence of new types of equivalence transformations of the Lagrangian density within a fixed coordinate system which cannot be derived through gauge transforms. The methodology to explicitly work out such transformations will be explored in subsequent papers.

The reader should be aware of the fact that the content of this section is mainly conceptual and it should be considered of a conjectural nature. Furthermore, such new types of equivalence transformations should not be construed as exhaustive in the sense that, when combined with the known equivalence transformations, they are not conceived as to produce a classification of all possible equivalence transformations.

For the reader's convenience, let us recall the equivalence transformations of the Lagrangian density used nowadays, which essentially are:

I. Those induced by transformations of the coordinates $x \rightarrow x'$. This class is dominated by the Lorentz transformations

$$ x \rightarrow x' = A^{-1}(x - \sigma), $$

$$ \mathcal{L} \rightarrow \mathcal{L}' = \gamma \mathcal{L}. $$

(9.1)

II. Those induced by transformations of the fields $\phi_a(x) \rightarrow \phi_a'(x)$ within a fixed coordinate system. This class is dominated by Abelian gauge transforms of the first type [38],

$$ \phi_a(x) \rightarrow \phi_a'(x) = e^{-ie\sigma_a}\phi_a(x), $$

$$ \bar{\phi}_a(x) \rightarrow \bar{\phi}_a'(x) = e^{+ie\sigma_a}\bar{\phi}_a(x), $$

(9.2)

or by the non-Abelian gauge transforms of the first type,

$$ \phi_a(x) \rightarrow \phi_a'(x) = e^{-ie\omega_a}\phi_a(x), $$

$$ \bar{\phi}_a(x) \rightarrow \bar{\phi}_a'(x) = e^{+ie\omega_a}\bar{\phi}_a(x), $$

(9.3)
or by the gauge transforms of the second type

\[ \phi_a(x) \rightarrow \phi_a'(x) = e^{-ie_a\theta(x)} \phi_a(x), \]

\[ \phi_a(x) \rightarrow \phi_a'(x) = e^{-ie_a\theta(x)} \phi_a(x), \]

(9.4)

with the corresponding mapping of the Lagrangian density

\[ \mathcal{L}(x_a, \phi^i, \phi'^i) \rightarrow \mathcal{L}^{GT}(x_a, \phi'^i, \phi'^{e'i}), \]

(9.5)

When \( \mathcal{L}^{GT} = \mathcal{L} \) we have a global or local gauge invariance depending on whether the gauge transform is of the first or second type, respectively.

We now postulated the existence of a third class of equivalence transformations of the Lagrangian density and in particular,

III. Those induced by transformations of the field equations within a fixed coordinate system and gauge.

The underscored sentence explicitly means that those transformations should occur independently of possible Lorentz and gauge transformations without prohibiting the combined use of transformations of type I, II, and III.

The possible existence of transformations of type III is implicit in our definition of “analytic representation.” Suppose that a quasi-linear system of tensorial field equations

\[ [A^a_{\nu} \phi^b \nu + B_a] = 0 \]

(9.6)

is assigned in a given ordering, and suppose that a Lagrangian density \( \mathcal{L}(x_a, \phi^i, \phi'^{e'i}) \) for its ordered direct representation

\[ \mathcal{L}_a(\phi) \equiv A^a_{\nu} \phi^b \nu + B_a = 0 \]

(9.7)

exists. But, system (9.6) can be formulated in an infinite variety of equivalent forms, e.g.,

\[ A^a_{\nu} \phi^b \nu + B_a = h^b (A^a_{\nu} \phi'^{e'i}) + B_b. \]

(9.8)

Notice that all the above equivalent forms occur within a fixed coordinate system and gauge by assumption. Suppose now that a new Lagrangian density \( \mathcal{L}^\ast(x_a, \phi^i, \phi'^{e'i}) \) for the (ordered) representation of at least one element of the class (9.8) exists with nontrivial factor functions, i.e.,

\[ \mathcal{L}^\ast(\phi) = A^a_{\nu} \phi'^{e'i} \nu + B_a^\ast = 0. \]

(9.9)

Then the systems of Lagrange equations in \( \mathcal{L} \) and \( \mathcal{L}^\ast \) do not coincide, i.e.,

\[ \mathcal{L}_a \neq \mathcal{L}_a^\ast, \]

(9.10)
A LAGRANGIAN IN FIELD THEORY. I

at least for some values of the index $a$ (unless $h^a_b = \delta^a_b$), but the mapping

$$L(x, \phi^a, \phi^{\dagger a}) \rightarrow L^a(x, \phi^a, \phi^{\dagger a})$$

(9.11)

is an equivalence mapping because the Lagrange equations in $L$ and $L^a$ are equivalent by construction. Thus, equivalence transformations of type (9.11), when they exist, must necessarily be of type III above.

A simple example is useful to illustrate this concept. Consider the conventional Lagrangian (8.7) for the free complex scalar field, i.e.,

$$L = \phi^{\dagger a} \phi^a - m^2 \phi \phi,$$

(9.12)

and suppose that the representation is direct,

$$(L_a(\phi)) \equiv \left( \begin{array}{c} \phi \phi^a \\ \phi^{\dagger a} \phi \end{array} \right) = 0,$$

(9.13)

i.e., the field equations are assumed in the ordering ($\phi^a \phi$). But, as indicated in Section 8, the same system can equivalently be represented by the new Lagrangian.

$$L^a = \frac{1}{2}(\phi^a \phi^{\dagger a} - m^2 \phi^a) + \text{c.c.},$$

(9.14)

and the indirect representation

$$(L^a_\phi(\phi)) = \left( \begin{array}{c} 0 \\ \phi \phi^a \\ \phi^{\dagger a} \phi \\ 0 \end{array} \right) = 0.$$
Lagrangians (9.12) to (9.14) can be written in terms of definition (9.16) in one of the equivalent two ways,

\[
\begin{pmatrix}
L^0 \\
L^1
\end{pmatrix}_S = \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix} \begin{pmatrix}
L^0 \\
L^1
\end{pmatrix}_S,
\]

\[
\begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix} \begin{pmatrix}
L^0 \\
L^1
\end{pmatrix}_S = \begin{pmatrix}
L^0 \\
L^1
\end{pmatrix}_S,
\]

and thus, it constitutes a simple example of isotopic transformation of the Lagrange equations. Other less trivial examples will be worked out in subsequent papers.

The corresponding transition

\[\mathcal{L} \rightarrow \mathcal{L}^*\]

will be termed an isotopic transformation of the Lagrangian density.

We are now in a position to identify the major objectives of our program. Our initial objectives are to investigate the significance of the conditions of self-adjointness for the problem of the necessary and sufficient conditions for the existence of ordered direct analytic representations of Lorentz-covariant tensorial field equations in the quasi-linear form; to identify a methodology for the construction of a Lagrangian, when it exists, from the given field equations; and to explore the significance of the underlying methodology for the structure of the Lagrangian capable of representing interactions. The above aspects are considered in paper II.

Our subsequent objectives are to perform a variational analysis of the equivalence transformations of quasi-linear field equations within a fixed coordinate system and gauge; to extend the analysis of the problem of the existence of a Lagrangian to the case of ordered indirect analytic representations; and to investigate some methodological aspects which underly the generalized Lagrange equations of type (8.5), with particular reference to their derivation from an action principle and their use within the context of the analytic representations. These additional problems are considered in paper III.

We shall then attempt, in a subsequent paper, the use of the above methodology within the context of the transformation theory, with particular reference to the explicit construction of the isotopic transformations of the Lagrangian density. In this respect let us remark that the rule (9.16), in view of the regularity of the factor functions, can always be reduced to the form

\[L^a_n(\phi) = g^a[bL_0(\phi)],\]

where the Lagrangian of the rhs is known and the possible identification of the Lagrangian of the lhs is requested for suitable factor terms \(g^a\). Now, the rhs of Eqs. (9.19) can be considered as an ordinary quasi-linear system of field equations.
Therefore, the knowledge of the necessary and sufficient conditions for the existence of a Lagrangian are crucial to ascertain the conditions under which the new Lagrangian \( \mathcal{L}_n \) exists. The knowledge of a method to compute a Lagrangian will then allow us to identify \( \mathcal{L}_n \), when it exists. Finally, the knowledge of the implications of this methodology for the problem of the structure of the Lagrangian capable of representing interactions will allow us to study some implications of the isotopic transformations within the context of the problem of interactions.

The extension of the above analysis to other frameworks, e.g., for spinorial or degenerate field equations, is tentatively contemplated as a subsequent step.

APPENDIX A: PROOF OF THEOREM 6.2

We shall prove Theorem 6.2 by particularizing the conditions of self-adjointness (6.10) for the quasi-linear form

\[
F_a = [A^\mu_{ab}(x_a, \phi_a^c, \phi^c_{ab}) \phi^b_{ab} + B_a(x_a, \phi_a^c, \phi^c_{ab})]^{\alpha \beta} = 0, \quad (A.1a)
\]

\[
A^\mu_{ab} = A^\mu_{ba}, \quad (A.1b)
\]

where property (A.1b) is extended to redefinitions \( A^\mu_{ab} \rightarrow A'^\mu_{ab} = \frac{1}{2}(A^\mu_{ab} + A^\mu_{ba}) \).

To simplify the computations, we introduce the notation

\[
F_{a}^{ab} \equiv \frac{\partial F_a}{\partial \phi^b}, \quad F_{a}^{ab} \equiv \frac{\partial F_a}{\partial \phi^b_{ab}}, \quad F_{a}^{ab} \equiv \frac{\partial F_a}{\partial \phi^b_{aa}}, \quad \text{etc.} \quad (A.2)
\]

Then, conditions (6.10) become

\[
F_{a}^{ab} = F_{b}^{ab} = F_{b}^{ba}, \quad (A.3a)
\]

\[
F_{a}^{ab} + F_{b}^{ab} - 2(F_{b}^{ab} \phi^c_{ab}) \phi^c_{ab} - 2(F_{b}^{ab} \phi^c_{ab}) \phi^c_{ab} = 0, \quad (A.3b)
\]

\[
-F_{a}^{ab} + F_{b}^{ab} + \frac{1}{2}(F_{a}^{ab} - F_{b}^{ab}) \phi^c_{ab} + \frac{1}{2}(F_{b}^{ab} - F_{b}^{ab}) \phi^c_{ab} = 0, \quad (A.3c)
\]

where we have ignored a possible explicit dependence of the equations in \( x_a \).

The specialization of conditions (A.3) to system (A.1) can be written

\[
A^\mu_{ab} = A^\mu_{ba} = A^\mu_{ba}, \quad (A.4a)
\]

\[
(A_{ac}^{ab} + A_{ba}^{ac} - 2A_{bc}^{ab}) \phi^c_{ab} + [(B_{a}^{ab} + B_{b}^{ab}) - 2(A_{bc}^{ab}) \phi^c_{ab}] = 0, \quad (A.4b)
\]
\[ \frac{1}{2}(A_{abc} - A_{bac}) \phi_{c}^{ij} + \frac{1}{3}(A_{adb}^{a} a - A_{bad}^{b} a) \phi_{a}^{ij} \]
\[ \quad + \frac{1}{3}(A_{bac}^{b} e - B_{bac}^{b} e) + (A_{ab}^{a} a - A_{ba}^{a} a) \phi_{a}^{ij} + 2(A_{bo}^{e} e - A_{oe}^{e} b) \phi_{e}^{ij} \]
\[ + \frac{1}{3}(B_{ba}^{b} c - B_{ab}^{b} c) \phi_{c}^{ij} - (B_{a b}^{i} - B_{b a}^{i}) = 0. \quad (A.4c) \]

For such conditions to hold identically, it is necessary that the following sets of conditions hold individually:

\[ A_{ab}^{i} = A_{ba}^{i} = A_{ba}^{i}, \quad (A.5a) \]
\[ A_{ab}^{i} = A_{ba}^{i} = A_{ab}^{i}, \quad (A.5b) \]
\[ B_{ab}^{i} + B_{ba}^{i} = 2(A_{ab}^{i} a) \phi_{a}^{ij}, \quad (A.5c) \]
\[ B_{ab}^{i} = 2(A_{ab}^{i} a) \phi_{a}^{ij}, \quad (A.5d) \]
\[ B_{ab}^{i} = 2(A_{ab}^{i} a) \phi_{a}^{ij}, \quad (A.5e) \]

\[ \frac{1}{3}(B_{ab}^{a} c - B_{ab}^{b} c) + (A_{ab}^{a} a - A_{ab}^{b} a) \phi_{a}^{ij} + 2(A_{ab}^{a} a - A_{ab}^{b} a) \phi_{a}^{ij} = 0, \quad (A.5f) \]
\[ B_{ab}^{a} - B_{ab}^{b} a - \frac{1}{2}(A_{ab}^{a} a - B_{ab}^{b} a) \phi_{a}^{ij} = 0, \quad (A.5g) \]

where horizontal bars denote symmetrization of the indicated indices. Explicitly, Eqs. (A.5b), (A.5d), (A.5e), and (A.5f) read

\[ A_{ab}^{i} + A_{ba}^{i} = A_{ab}^{i} + A_{ba}^{i}, \quad (A.5b') \]
\[ A_{ab}^{i} + A_{ba}^{i} + A_{ab}^{i} = A_{ab}^{i} + A_{ba}^{i} + A_{ba}^{i}, \quad (A.5d') \]
\[ A_{ab}^{i} + A_{ba}^{i} + A_{ab}^{i} + A_{ba}^{i} = A_{ab}^{i} + A_{ba}^{i} + A_{ba}^{i}, \quad (A.5e') \]
\[ \frac{1}{3}(B_{ab}^{a} c - B_{ab}^{b} c) + \frac{1}{2}(B_{ab}^{a} c - B_{ab}^{b} c) \phi_{a}^{ij} + (A_{ab}^{a} a - A_{ab}^{b} a) \phi_{a}^{ij} + 2(A_{ab}^{a} a - A_{ab}^{b} a) \phi_{a}^{ij} = 0. \quad (A.5f') \]
We must now identify among Eqs. (A.5) the set of all independent conditions of self-adjointness for the quasi-linear form (A.1).

Let us divide conditions (A.5) into three sets:

1. Equations (A.5a), (A.5c), and (A.5g), i.e.,
   \[ A_{ab}^{\mu} = A_{ba}^{\mu} = A_{ab}^{\mu}, \]  
   \[ B_{a b}^{\mu} + B_{b a}^{\mu} = 2(A_{b a}^{\mu}) \phi_{b}^{\mu}, \]  
   \[ B_{a b}^{\mu} - B_{b a}^{\mu} = \frac{1}{3}(B_{a b c}^{\mu} - B_{b a c}^{\mu}) \phi_{a b}^{\mu}. \]

2. Equations (A.5b), (A.5d), and (A.5e), which involve only derivatives of the \( A \) terms, i.e.,
   \[ A_{a e b}^{\mu} + A_{b e a}^{\mu} = A_{ba e}^{\mu}, \]  
   \[ A_{a b e}^{\mu} = A_{b a e}^{\mu}, \]  
   \[ A_{a d b}^{\mu} = A_{b d a}^{\mu}. \]

3. The remaining Eqs. (A.5f)
   \[ \frac{1}{3}(B_{a b c}^{\mu} - B_{b a c}^{\mu}) + (A_{b a d}^{\mu}) \phi_{b}^{\mu} + 2(A_{b e a}^{\mu} - A_{e b a}^{\mu}) = 0. \]

All conditions (A.5) of set I are clearly independent among themselves and with respect to conditions (A.7) and (A.8). Therefore, they constitute a first independent subset of the conditions of self-adjointness.

Among the conditions of set 2, Eqs. (A.7a) are independent. To see this, it is sufficient to show that they imply Eqs. (A.7b). Indeed, by considering Eqs. (A.7a) in the two equivalent forms
   \[ A_{a e b}^{\mu} = -A_{b e a}^{\mu} + A_{ba e}^{\mu} = A_{ba e}^{\mu}, \]  
   \[ A_{a b e}^{\mu} = -A_{ba e}^{\mu} + A_{a e b}^{\mu} = A_{a e b}^{\mu}, \]

and by subtracting, we obtain
   \[ A_{a e b}^{\mu} - A_{a b e}^{\mu} = -A_{b e a}^{\mu} + A_{ba e}^{\mu} + A_{ba e}^{\mu} - A_{b e a}^{\mu} = 0, \]

which hold identically in view of Eqs. (A.6a), and, as such, are equivalent to Eqs. (A.7b). Conditions (A.7c) are also independent because they cannot be
derived from conditions (A.7a). Indeed, by performing partial derivatives of Eqs. (A.7a) with respect to $\phi^d_\alpha$, and by rearranging the indices, we can write expressions of the type

$$
+ A^{\alpha_2 \alpha_1}_{\beta_2 \beta_1} - A^{\beta_2 \beta_1}_{\alpha_2 \alpha_1} = - A^{\alpha_2 \beta_1}_{\beta_2 \alpha_1} + A^{\alpha_2 \beta_1}_{\alpha_2 \beta_1} + A^{\beta_2 \alpha_1}_{\alpha_2 \beta_1} - A^{\beta_2 \beta_1}_{\alpha_2 \alpha_1},
$$

$$
+ A^{\beta_2 \beta_1}_{\alpha_2 \alpha_1} = - A^{\alpha_2 \beta_1}_{\beta_2 \alpha_1} + A^{\alpha_2 \beta_1}_{\alpha_2 \beta_1} + A^{\beta_2 \alpha_1}_{\alpha_2 \beta_1} - A^{\beta_2 \beta_1}_{\alpha_2 \alpha_1},
$$

(A.11)

and similarly for other terms. The above equations fail to reproduce Eqs. (A.7c) through any of their possible linear combinations. Notice, in particular, that if we add equations of type (A.11) we obtain a trivial identity, and not Eqs. (A.7c).

Conditions (A.7a) and (A.7c) are also independent with respect to the set of conditions 1, i.e., Eqs. (A.6). To prove that they are actually independent we must now prove that they are so with respect to the combined set of conditions 1 and 3.

Let us first see whether conditions (A.8) can be derived from Eqs. (A.6). Clearly, the only possibility is offered by using partial derivatives of Eqs. (A.6b) with respect to derivatives of the fields, which can be written

$$
+ \frac{1}{2}(B^{a_{1}a_{2}}_{\alpha} + B^{a_{2}a_{1}}_{\alpha}) - (A^{a_{1}a_{2}}_{\alpha} + A^{a_{2}a_{1}}_{\alpha}) \phi^{d}_{\alpha} - A^{a_{1}a_{2}}_{\alpha} = 0,
$$

$$
- \frac{1}{2}(B^{a_{1}a_{2}}_{\alpha} + B^{a_{2}a_{1}}_{\alpha}) + (A^{a_{1}a_{2}}_{\alpha} + A^{a_{2}a_{1}}_{\alpha}) \phi^{d}_{\alpha} + A^{a_{1}a_{2}}_{\alpha} = 0,
$$

(A.12)

$$
+ \frac{1}{2}(B^{a_{1}a_{2}}_{\alpha} + B^{a_{2}a_{1}}_{\alpha}) - (A^{a_{1}a_{2}}_{\alpha} + A^{a_{2}a_{1}}_{\alpha}) \phi^{d}_{\alpha} - A^{a_{1}a_{2}}_{\alpha} = 0,
$$

$$
- \frac{1}{2}(B^{a_{1}a_{2}}_{\alpha} + B^{a_{2}a_{1}}_{\alpha}) + (A^{a_{1}a_{2}}_{\alpha} + A^{a_{2}a_{1}}_{\alpha}) \phi^{d}_{\alpha} + A^{a_{1}a_{2}}_{\alpha} = 0.
$$

By summing up we obtain

$$
\frac{1}{2}(B^{a_{1}a_{2}}_{\alpha} + B^{a_{2}a_{1}}_{\alpha} - B^{a_{1}a_{2}}_{\alpha} - B^{a_{2}a_{1}}_{\alpha})
$$

$$
- (A^{a_{1}a_{2}}_{\alpha} + A^{a_{2}a_{1}}_{\alpha} - A^{a_{1}a_{2}}_{\alpha} - A^{a_{2}a_{1}}_{\alpha}) \phi^{d}_{\alpha} - 2(A^{a_{1}a_{2}}_{\alpha} - A^{a_{2}a_{1}}_{\alpha}) = 0,
$$

(A.13)

which does not coincide with Eqs. (A.8). However, by subtracting Eqs. (A.8) and (A.13) we obtain the conditions

$$
[(A^{a_{1}a_{2}}_{\alpha} + A^{a_{2}a_{1}}_{\alpha} - A^{a_{1}a_{2}}_{\alpha} - A^{a_{2}a_{1}}_{\alpha}) \phi^{d}_{\alpha} = 0,
$$

(A.14)

where we have used Eqs. (A.6a). But Eqs. (A.14) are not independent because they can be obtained from Eqs. (A.7b). As a consequence, Eqs. (A.3) themselves are not independent.
A LAGRANGIAN IN FIELD THEORY. I

The set of all independent conditions of self-adjointness for the quasi-linear form is thus given by

\[ A_{ab}^{\mu\nu} = A_{ba}^{\mu\nu} = A_{a0}^{\mu} \quad , \]  

(A.15a)

\[ A_{e}\!e_{a}^{\mu} + A_{b}\!e_{a}^{\mu} = A_{a}\!e_{\!e}^{\mu} \quad , \]  

(A.15b)

\[ A_{a}^{\mu\nu} A_{e d}^{\mu\nu} = A_{e}^{\mu\nu} A_{a d}^{\mu\nu} \quad , \]  

(A.15c)

\[ B_{a}^{\mu} \quad , \]  

(A.15d)

\[ B_{a}^{\mu} - B_{a}^{\mu} = 2 (\sigma_{a b}^{\mu}) \phi_{\!e}^{\!\mu} \quad , \]  

(A.15e)

and they coincide with Eqs. (6.14) once the possible explicit dependence of Eqs. (A.1) in the coordinates \( x_{a} \) is taken into account. Theorem 6.2 then follows from the uniqueness of the adjoint.

APPENDIX B: PROOF OF THEOREM 6.3

We shall prove Theorem 6.3 by using conditions of self-adjointness (6.10) for the semilinear form

\[ F = [g^{\mu\nu} \phi_{a}^{\mu\nu} - f_{a}(x, \phi, \phi^{ci})] \phi^{ci} = 0. \]  

(B.1)

Conditions (6.10a), i.e.,

\[ \frac{\delta F_{a}}{\delta \phi^{ci}_{a}} = \frac{\delta F_{a}}{\delta \phi^{ci}_{a}} = \delta_{a b} \otimes g^{\mu\nu} = \delta_{a b} \otimes g^{\mu\nu} \]  

(B.2)

are identically verified and can be ignored.

Conditions (6.10b) read

\[ \frac{\delta F_{a}}{\delta \phi^{ci}_{a}} + \frac{\delta F_{a}}{\delta \phi^{ci}_{a}} = \frac{\delta f_{a}}{\delta \phi^{ci}_{a}} + \frac{\delta f_{a}}{\delta \phi^{ci}_{a}} = 0, \]  

(B.3)

and constitute a first independent set of conditions.

Conditions (6.10c) become

\[ \frac{\delta f_{a}}{\delta \phi^{b}} - \frac{\delta f_{b}}{\delta \phi^{c}} = \frac{1}{2} \left[ \phi_{a}^{c} \phi_{b}^{c} \frac{\partial}{\partial \phi^{ci}_{a}} \left( \frac{\partial f_{a}}{\partial \phi^{ci}_{a}} - \frac{\partial f_{b}}{\partial \phi^{ci}_{a}} \right) \right] + \frac{1}{2} \left( \frac{\partial^{2} f_{a}}{\partial \phi^{ci}_{a} \partial \phi^{ci}_{a}} - \frac{\partial^{2} f_{b}}{\partial \phi^{ci}_{a} \partial \phi^{ci}_{a}} \right) \phi^{ci}_{ci}. \]  

(B.4)
and can hold identically iff the following two separate sets of conditions,

\[
\frac{\partial^2 f_a}{\partial \phi^{\delta^a}_{\alpha}} \frac{\partial^2 f_a}{\partial \phi^{\delta^b}_{\beta}} - \frac{\partial^2 f_b}{\partial \phi^{\delta^a}_{\alpha}} \frac{\partial^2 f_b}{\partial \phi^{\delta^b}_{\beta}} = 0,
\]

(B.5)

\[
\frac{\partial f_a}{\partial \phi^{\delta^a}_{\alpha}} - \frac{\partial f_b}{\partial \phi^{\delta^b}_{\beta}} = \frac{1}{2} \left( \delta^a_{\alpha} + \phi^{\delta^a}_{\alpha} \frac{\partial}{\partial \phi^{\delta^a}_{\alpha}} \left( \frac{\partial f_a}{\partial \phi^{\delta^b}_{\beta}} - \frac{\partial f_b}{\partial \phi^{\delta^b}_{\beta}} \right) \right).
\]

hold. The horizontal bar again denotes symmetrization of the indicated indices, as in Appendix A.

Summarizing, the set of all independent conditions of self-adjointness of the semilinear form (B.1) is

(B.6a)

(B.6b)

(B.6c)

Now, the combination of Eqs. (B.6b) with partial derivatives of (B.6a) yields expressions of the type

(B.7)

Therefore, a necessary (but not sufficient) condition for the semilinear form (B.1) to be self-adjoint is that it is linear in the derivatives \( \phi^a \).

This demands that Eqs. (B.1) be of the form

(B.8)

We must now specialize conditions (B.6) for Eqs. (B.8). Conditions (B.6b) become

(B.9)

and constitute a first independent set of conditions. Finally, Eqs. (B.6c) become

(B.10)
and, by using conditions (B.3), can be written

$$\left( \frac{\partial \rho^{a}_{c}}{\partial \phi^{b}} + \frac{\partial \rho^{b}_{c}}{\partial \phi^{a}} + \frac{\partial \rho^{c}_{a}}{\partial \phi^{b}} \right) \phi^{c} + \left( \frac{\partial \rho^{a}_{b}}{\partial \phi^{c}} + \frac{\partial \rho^{c}_{b}}{\partial \phi^{a}} - \frac{\partial \rho^{b}_{c}}{\partial \phi^{a}} \right) = 0. \quad (B.11)$$

The above conditions can hold everywhere in the subregion $R_{st}$ of $R_{SL}$ with points $(x_{a}, \phi^{a})$ iff each term within brackets individually vanishes. In this way we reach the set of all independent conditions of self-adjointness of the semilinear form (B.8)

$$\rho^{a}_{ab} + \rho^{a}_{ba} = 0,$$

$$\frac{\partial \rho^{c}_{a}}{\partial \phi^{b}} + \frac{\partial \rho^{b}_{c}}{\partial \phi^{a}} + \frac{\partial \rho^{a}_{b}}{\partial \phi^{c}} = 0, \quad (B.12)$$

$$\frac{\partial \rho^{a}_{b}}{\partial \phi^{c}} = \frac{\partial \rho^{c}_{a}}{\partial \phi^{b}} - \frac{\partial \rho^{b}_{c}}{\partial \phi^{a}}.$$ 

This completes the proof of Theorem 6.3.

**APPENDIX C: PROOF OF REPRESENTATION (8.19)**

Consider the system of field equations for a complex scalar field in interaction with the electromagnetic field

$$(F_{a}) = \begin{pmatrix} -g^{\mu\nu} A_{\mu}^{\nu} + ie(\phi^{i}_{a} + i e A_{\mu}^{\nu} \phi - \phi (\phi^{i}_{a} - i e A_{\mu} \phi)) \\ g^{\mu\nu} \phi^{i}_{a} + m^{2} \phi^{i} - e^{2} A_{\mu}^{\nu} \phi^{i} - ie A_{\mu}^{i} \phi - 2ie A_{\mu}^{\nu} \phi^{i}_{a} \\ g^{\mu\nu} \phi^{i}_{a} + m^{2} \phi^{i} - e^{2} A_{\mu}^{\nu} \phi^{i} + ie A_{\mu}^{i} \phi + 2ie A_{\mu}^{\nu} \phi^{i}_{a} \end{pmatrix} = 0, \quad (C.1)$$

and its indirect representation in terms of the Lagrange equations

$$L_{a}(\phi) \equiv d_{a}[(\partial_{a} L/\partial \phi^{a})] - (\partial L/\partial \phi^{a}) = 0 \quad (C.2)$$

in the Lagrangian density

$$L = -\frac{1}{2} A_{\mu}^{\nu} A^{\mu \nu} + \phi^{i} \phi^{i} - m^{2} \phi^{i} - e^{2} A_{\mu}^{\nu} \phi^{i} - ie(\phi^{i} \phi^{i} - \phi \phi^{i}) A^{\mu}, \quad (C.3)$$

where we have ignored the Lorentz gauge $A_{a}^{*a} = 0$.

We shall assume the ordering

$$\{\phi^{a}\} = \{A_{0}, A_{1}, A_{2}, A_{3}, \phi, \phi \},$$

$$a = 1, 2, 3, 4, 5, 6. \quad (C.4)$$
Then the analytic representation explicitly reads

\[
(L_\alpha) = \begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix} \begin{pmatrix}
-\Box A^u + ie(\bar{\phi}_u + ieA_u \phi) \phi - \bar{\phi}(\phi^*_u - ieA_u \phi) \\
-\Box + m^2 - e^2 A_u A^u - ieA_u \phi \phi + 2ieA^u \partial^u \phi \\
-\Box + m^2 - e^2 A_u A^u + ieA_u \partial^u \phi + 2ieA^u \partial^u \phi
\end{pmatrix} = 0.
\]

(C.5)

Our objective is to prove that the above representation is of the indirect type

\[
[L_\alpha(\phi)]_{\text{ind}} = [b_u^a(F_2)_{\text{NSA}}]_{\text{ind}},
\]

(C.6)

which is precisely the case of Eqs. (8.19), or, more explicitly, that the field equations in the form and ordering (C.1) are non-self-adjoint; nevertheless, after the permutation induced by the factor of Eqs. (C.5), they become self-adjoint.

In view of the rather elaborate but straightforward calculations involved, it is here advisable to first work out the corresponding Newtonian limit [3]. This might also provide some insight into the structure of the gauge invariant theories which will be useful for our analysis of paper II.

Perform the limits

\[
\begin{align*}
x_\mu &\to t(x = 0, 1, 2, 3), \quad \phi(x) \to m^2 q_1(t), \quad \bar{\phi}(x) \to m^2 q_2(t), \\
i \in A_u &\to b/2m = \text{const} (\mu = 0, 1, 2, 3), \quad m^2 - e^2 A_u A^u \to k/m = \text{const}, \\
d_u &\to (d/dt) (\mu = 0, 1, 2, 3).
\end{align*}
\]

(C.7)

Then Lagrangian (C.3) becomes

\[
L \to L = m \ddot{q}_1 \ddot{q}_2 + \frac{1}{2} b(q_1 \dot{q}_2 - \dot{q}_1 q_2) - k q_1 q_2,
\]

(C.8)

namely, it recovers a known model for nonconservative Newtonian systems introduced by Morse and Feshbach [39].

Consider the Newtonian equations of motion

\[
\begin{align*}
\ddot{q}_1 + b \dot{q}_1 + k q_1 &= 0, \\
\ddot{q}_2 - b \dot{q}_2 + k q_2 &= 0,
\end{align*}
\]

(C.9)

in the ordering \((q_1, q_2)\). It is easy to see that the above equations are non-self-adjoint. Indeed, the conditions of self-adjointness, which for this case are easily derivable from Eqs. (6.3), are

\[
\begin{align*}
e_{ab} - e_{ba} &= 0, \\
b_{ab} + b_{ba} &= 2a_{ab} = 0, \\
a_{ab} - a_{ba} &= \frac{1}{2} (b_{ab} - b_{ba}) = 0,
\end{align*}
\]

(C.10)
and are clearly violated by Eqs. (C.9). This can be seen more transparently by writing such equations in the matrix form

\[
\begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}
\begin{pmatrix}
\tilde{q}_1 \\
\tilde{q}_2
\end{pmatrix}
+ \begin{pmatrix}
b & 0 \\
0 & -b
\end{pmatrix}
\begin{pmatrix}
\tilde{q}_1 \\
\tilde{q}_2
\end{pmatrix}
+ \begin{pmatrix}
k & 0 \\
0 & k
\end{pmatrix}
\begin{pmatrix}
q_1 \\
q_2
\end{pmatrix}
= c_{ab}\tilde{q}_b + a_{ab}\tilde{q}_b + c_{ab}q_b = 0, \quad a, b = 1, 2. \tag{C.11}
\]

Thus, the violation occurs because of the \( b \) coefficients.

Consider now the above equations after a permutation of the indices, i.e.,

\[
\begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
\begin{pmatrix}
\tilde{q}_1 \\
\tilde{q}_2
\end{pmatrix}
+ \begin{pmatrix}
b & 0 \\
0 & -b
\end{pmatrix}
\begin{pmatrix}
\tilde{q}_1 \\
\tilde{q}_2
\end{pmatrix}
+ \begin{pmatrix}
k & 0 \\
0 & k
\end{pmatrix}
\begin{pmatrix}
q_1 \\
q_2
\end{pmatrix}
= \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
\begin{pmatrix}
\tilde{q}_1 \\
\tilde{q}_2
\end{pmatrix}
+ \begin{pmatrix}
b & 0 \\
0 & -b
\end{pmatrix}
\begin{pmatrix}
\tilde{q}_1 \\
\tilde{q}_2
\end{pmatrix}
+ \begin{pmatrix}
k & 0 \\
0 & k
\end{pmatrix}
\begin{pmatrix}
q_1 \\
q_2
\end{pmatrix}
= c'_{ab}\tilde{q}_b + b'_{ab}\tilde{q}_b + a'_{ab}q_b = 0, \quad a, b = 1, 2. \tag{C.12}
\]

It is easy to see that the equations of motion in this new form become self-adjoint. Indeed, all conditions of self-adjointness (C.10) are satisfied by Eqs. (C.12).

It is now a matter of simple inspection to see that the Morse–Feshbach Lagrangian (C.8) induces an analytic representation of the equations of motion in their self-adjoint form (C.12) rather than in their non-self-adjoint form (C.11), i.e.,

\[
\begin{pmatrix}
\frac{d}{dt} & \frac{\partial L}{\partial q_1} - \frac{\partial L}{\partial \dot{q}_1} \\
\frac{d}{dt} & \frac{\partial L}{\partial q_2} - \frac{\partial L}{\partial \dot{q}_2}
\end{pmatrix}_{SA}
= \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}
\begin{pmatrix}
\dot{q}_1 + bq_1 + kq_2 \\
\dot{q}_2 - bq_2 + kq_2
\end{pmatrix}_{SA} = 0. \tag{C.13}
\]

This is precisely an example of structures (C.6).

Notice that the transition from form (C.11) to form (C.12) corresponds in practice to an inversion of the ordering. This indicates the significance of the ordering within the context of the problem of the structure of analytic representations.

It should be indicated that the Newtonian limit of the derivative couplings of the gauge equations (C.1) is constituted by nonconservative forces, namely, forces which are not derivable from a potential function. Indeed, this is precisely the case of the acting force of both Eqs. (C.11) and (C.12), with components \( \mathbf{F} = (b\dot{q}_1, -b\dot{q}_2) \). Despite that, a Lagrangian for the representation of this system does exist and its existence can ultimately be related precisely to the inversion of the ordering of the analytic representation (C.13). This feature, which directly extends to field theories, is peculiar to all theories with gauge invariant terms of the type \( \phi \). We shall come back to the above remarks in paper II within the context of the problem of the structure of the Lagrangian capable of representing interactions.
We now study the field theoretical case of the representation (C.6) with Lagrangian (C.3). In this case the computations are considerably more involved, although straightforward. In order to avoid possible misinterpretation of the underlying concepts, the reader should keep in mind that, on conceptual grounds, all the above indicated features of the Newtonian representation (C.13) directly extend to the field theoretical case of the Lagrangian (C.3).

Due to the vital significance of Theorem 7.1 to our analysis, let us begin with its verification for the case of Lagrangian (C.3).

The Jacobi equations (7.10) in the variations

\[
\{ \delta A_u, \delta \varphi, \delta \bar{\varphi} \} = w(\eta_u, \eta_\varphi, \eta_{\bar{\varphi}}), \quad w \in O, \tag{C.14}
\]

reduce in this case to

\[
\Omega_\eta(\eta) = \left\{ \begin{array}{l}
\frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}} \eta^{\alpha u} + \left( \frac{\partial^2 \mathcal{L}}{\partial \varphi_{\alpha u} \partial \varphi_{\beta v}} - \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}} \right) \eta^{\beta v} \\
+ \left[ d_u \left( \frac{\partial^2 \mathcal{L}}{\partial \varphi_{\alpha u} \partial \bar{\varphi}_{\beta v}} \right) - \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}} \right] \eta^v \end{array} \right. \tag{C.15}
\]

and are given by

\[
(\Omega_\eta(\eta)) = \begin{vmatrix}
-2e \bar{\varphi} \eta_u + ie(\bar{\varphi} \eta_u + 2ieA_u \bar{\varphi}) \eta_v - \eta_\varphi(\varphi_u - 2ieA_u \varphi) \\
- ie(\bar{\varphi} \eta_u - \varphi_\varphi \eta_u) \\
\eta_u + m^2 - e^2 A_u A^u + ieA_u \varphi \eta_\varphi - 2ie(\bar{\phi}^u + \bar{\varphi} \eta_u) \eta_u \\
\eta_u + 2ieA_u \eta_\varphi + ie \eta_u i^u \\
\eta_u - m^2 A_u A^u - ieA^u \varphi \eta_\varphi - 2ie(\bar{\phi}^u - ieA_u \varphi) \eta_u \\
- 2ie \varphi u \eta_u - ie \varphi u i^u
\end{vmatrix} \tag{C.16}
\]

where now all fields \(\{A_u, \varphi, \bar{\varphi}\} \) are assumed to be known solutions of Eqs. (C.1).

System (C.9) in the variations \(\{\eta_u, \eta_\varphi, \eta_{\bar{\varphi}}\} \) is significant per se, but we shall not indulge in its analysis at this time.

The adjoint system of variations (7.14) can now be written

\[
\Omega_\varphi(\eta) = \eta^{\alpha u} \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \varphi_{\beta v}} + \left( \frac{\partial^2 \mathcal{L}}{\partial \varphi_{\alpha u} \partial \varphi_{\beta v}} - \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}} \right) \eta^{\beta v} \\
+ \left[ d_u \left( \frac{\partial^2 \mathcal{L}}{\partial \varphi_{\alpha u} \partial \bar{\varphi}_{\beta v}} \right) - \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}} \right] \eta^v \tag{C.17}
\]

But the Lagrangian (C.3) satisfies the continuity condition of Theorem 7.1, i.e.,

\[
\frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\beta v} \partial \varphi_{\alpha u}} = \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}}, \quad \frac{\partial^2 \mathcal{L}}{\partial \varphi_{\alpha u} \partial \varphi_{\beta v}} = \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}}, \quad \frac{\partial^2 \mathcal{L}}{\partial \varphi_{\alpha u} \partial \bar{\varphi}_{\beta v}} = \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \varphi_{\beta v}}, \quad \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}} = \frac{\partial^2 \mathcal{L}}{\partial \bar{\varphi}_{\alpha u} \partial \bar{\varphi}_{\beta v}}. \tag{C.18}
\]
Then Eqs. (C.15) and (C.17) coincide, i.e.,
\[
\Omega_a(\eta) = \tilde{\Omega}_a(\eta), \quad a = 1, 2, \ldots, 8. \tag{C.19}
\]

Therefore, as expected from Theorem 7.1, the Lagrange equations in the gauge invariant Lagrangian (C.3) are self-adjoint. This also proves the self-adjointness of the rhs of representation (C.6) in the Lagrangian (C.3).

To study the rhs of the same representation, let us begin by studying the variational properties of the equations of motion in the form (C.1). The system of equations of variations is, from Eqs. (4.4),
\[
M_a(\eta) = \frac{\partial F_a}{\partial \dot{\eta}^a} \eta^b + \frac{\partial F_a}{\partial \dot{\phi}^{\alpha\beta}_a} \eta^{b\gamma} + \frac{\partial F_a}{\partial \dot{\phi}^{\alpha\beta\gamma}_a} \eta^{b\gamma}, \tag{C.20}
\]
and it coincides, up to the ordering of the same equations, with system (C.16). Now the adjoint system, from Eq. (5.6), is given by
\[
\tilde{M}_a(\eta) = \frac{\partial \bar{F}_a}{\partial \dot{\bar{\eta}}^a} \bar{\eta}^b - \frac{\partial \bar{F}_a}{\partial \dot{\bar{\phi}}^{\alpha\beta}_a} \bar{\eta}^{b\gamma} + \frac{\partial \bar{F}_a}{\partial \dot{\bar{\phi}}^{\alpha\beta\gamma}_a} \bar{\eta}^{b\gamma}. \tag{C.21}
\]

An explicit calculation, which is summarized in Table I, then shows that this system is not self-adjoint. This proves the non-self-adjointness of the internal system of the rhs of representation (C.6).

To complete the proof of the structure of the representation, we now repeat the above analysis with Eqs. (C.20) and (C.21) for the equivalent system
\[
(F^\text{Eq}_a) = \begin{pmatrix}
4 & 0 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0
\end{pmatrix}
\begin{pmatrix}
-\frac{\partial^\alpha A^{\alpha\beta}_a}{\partial x^\gamma} \eta^\gamma - \frac{\partial^\alpha A^{\alpha\beta}_a}{\partial x^\gamma} \phi^\gamma \\
\frac{\partial^\alpha A^{\alpha\beta}_a}{\partial x^\gamma} \eta^\gamma + \frac{\partial^\alpha A^{\alpha\beta}_a}{\partial x^\gamma} \phi^\gamma \\
\frac{\partial^\alpha A^{\alpha\beta}_a}{\partial x^\gamma} \eta^\gamma - \frac{\partial^\alpha A^{\alpha\beta}_a}{\partial x^\gamma} \phi^\gamma
\end{pmatrix} = 0. \tag{C.22}
\]

Explicit calculations then show that, as it is the case for the Newtonian limit (C.12), the above equivalent system is self-adjoint.

And indeed, the analytic representation induced by Lagrangian (C.3) produces the field equations in their self-adjoint, rather than their non-self-adjoint form, i.e.,
\[
[L^\alpha_a(\phi)]_{\text{SA}} = [F^\text{Eq}_a(\phi)]_{\text{SA}}, \quad a = 1, 2, \ldots, 6. \tag{C.23}
\]

This completes the proof of the structure of representation (8.19).

It is significant for our subsequent use to point out that the case of the analytic representation induced by the gauge invariant Lagrangian (C.3) constitutes an
example of what we have termed "ordered indirect analytic representation," namely, a representation for which each of the three sets of identities

\[
\begin{align*}
\mathcal{L}^a_0(\phi) & \equiv F^a_0(\phi), \\
\mathcal{L}^a_1(\eta) & \equiv \mathcal{M}^a_0(\eta), \\
\mathcal{L}^a_2(\eta) & \equiv \mathcal{N}^a_0(\eta),
\end{align*}
\]  
(C.24)

is verified (see Section 8). It is only when this is the case that the self-adjointness of the rhs of structure (C.6) is guaranteed. In turn, this property, as we shall see in paper II, is crucial for the problem of the necessary and sufficient conditions for the existence of a Lagrangian.

As a final remark, let us notice that while in ultimate analysis the question whether the representation is direct or indirect is immaterial (because it merely depends on the assumed form of field equations) the ordering requirement is crucial to guarantee the validity of all parts of Eqs. (C.24).

ACKNOWLEDGMENTS

It is a pleasure to thank Professors F. E. Low and R. Jackiw for the kind hospitality extended to me at the Center for Theoretical Physics of the Massachusetts Institute of Technology, where this work was done. I would also like to express my indebtedness to Professors H. Rund and D. Lovelock for their kind reception during my visit to the Department of Mathematics of the University of Arizona in Tucson, May 10–11, 1976, and for their many suggestions and remarks which proved to be very valuable for the finalization of this paper. Finally, I would like to thank Professors P. Dedecker, D. G. B. Edelean, P. Havas, R. Herman, and D. C. Spencer for correspondence on several technical points.

REFERENCES

1. We shall assume throughout this paper the convention on the sum of repeated Latin and Greek indices.
2. The identity sign here simply indicates that the \( k \)-component of the Lagrange equations coincides with the \( k \) component of the equations of motion in a given ordering.
7. H. Helmholtz, J. Reine Angew. Math. 100 (1887), 137.
14. We say that system (1.3) is regular (degenerate) in a (closed and connected) domain $E_{m+1}$ of points $t, q_1$, and $q_2$, when its functional determinant

$$d = \left| \frac{\partial F}{\partial q} \right| = | A_{ij} | (R_{2m+1})$$

is everywhere non-null (null) in it. Notice that this terminology does not appear to be universally used. Equivalent terms sometimes used in the current literature are nonsingular (singular) or standard (nonstandard).

24. It should be indicated that, to the best knowledge of this author, no currently available textbook on the calculus of variations presents a review of the inverse problem.
28. Within the Newtonian framework of Eqs. (1.3), $d = | A_{ij} | (R_{2m+1}) = d(R_{2m+1})$ is non-null as a function when the system is regular. However, the equation $d(R_{2m+1}) = 0$ may admit solutions. This does not contradict the condition of regularity because, according to our definition, a system is degenerate when it is null at a point of $R_{2m+1} = \{t, q_1, q_2\}$ and (at least) in its neighborhood. The situation for the field equations (3.1) is equivalent. The selection of the regions $R$ in which all our field equations are regular will be tacitly made as to exclude any zero of the functional determinant everywhere in the closure $R = R \cup \partial R$ of $R$. Notice that the study of the field equations in a point $(x, \phi, \phi', \phi^{(2)}\phi)$ and in its neighborhood is sufficient for our program.
34. It should be recalled that hyperbolic variational problems are generally vacuous, namely, they generally have no extremum irrespective of the boundary conditions ([22]). This aspect, which is insignificant for our analysis, will be considered in more detail in paper II.

35. An example of a Lagrangian density in two fields which is degenerate according to our terminology is given by

$$L = \frac{1}{2}(\phi_1^{nm} + \phi_2^{nm})(\phi_1^{\mu} + \phi_2^{\mu}) + L'(\phi_1, \phi_2).$$

In this case the functional determinant of the Lagrange equations is

$$d(L_{ld}) = \left| \frac{\partial^2 L}{\partial \phi_1^{\mu} \partial \phi_2^{\nu}} \right| = \left| g^\mu_\nu \ g^\nu_\mu \right| = 0.$$ 

This case is excluded within the context of this paper.
